A UNIFIED SEPARATION THEOREM FOR CLOSED SETS IN A BANACH SPACE AND OPTIMALITY CONDITIONS FOR VECTOR OPTIMIZATION∗

XI YIN ZHENG† AND KUNG FU NG‡

Abstract. Using the technique of variational analysis and in terms of normal cones, we establish unified separation results for finitely many closed (not necessarily convex) sets in Banach spaces, which not only cover the existing nonconvex separation results and a classical convex separation theorem but also recapture the approximate projection theorem. With help of the separation result for closed sets, we provide necessary and sufficient conditions for approximate Pareto solutions of constrained vector optimization problems. In particular, we extend some basic optimality results for approximate solutions of numerical optimization problems to the vector optimization setting.

Key words. Normal cone, Separation theorem, vector optimization, approximate Pareto solution

AMS subject classifications. 49J52, 90C25, 90C29

1. Introduction. The separation theorems for convex sets play a key role in functional analysis and optimization theory. The most well-known and useful version of these theorems is probably the following: if $A_1, A_2$ are disjoint closed convex sets in $X$ with one of them being compact then there exists a continuous linear functional $x^*$ on $X$ such that

$$\inf_{x \in A_2} \langle x^*, x \rangle > \sup_{x \in A_1} \langle x^*, x \rangle,$$

where $X$ is a Banach space (or more generally, a locally convex topological vector space). In order to focus on the main issues and also for the simplicity of presentation, we assume throughout that $X$ is a Banach space (we shall explicitly make clear if $X$ is required to satisfy additional assumption such as that $X$ is an Asplund space). In recent years, a lot of attention has been directed to study the more general case that $A_1, A_2$ are closed (not necessarily convex) subsets of $X$ (cf. [14, 22, 23] and references there in). In an Asplund space and in terms of Fréchet normal cone, Mordukhovich and Shao [15] first established the extremal principle for two closed sets with an extremal point (a special common point of these two sets). In some sense, this extremal principle can be regarded as a kind of fuzzy separation theorem for two nonconvex closed subsets. Further, Mordukhovich, Treiman and Zhu [17] introduced the extremal point concept for finitely many closed sets and established the extremal principle for finitely many closed sets. At this point, let us define the

so-called non-intersect index $\gamma(A_1,\cdots,A_n)$ by

$$
\gamma(A_1,\cdots,A_n) := \inf \left\{ \sum_{i=1}^{n-1} \|a_i - a_n\| : a_i \in A_i, \; i = 1,\cdots,n \right\}.
$$

Note that $\gamma(A_1,\cdots,A_n) = 0$ if $\bigcap_{i=1}^{n} A_i \neq \emptyset$ and that for any $\varepsilon > 0$ there exists $a_i \in A_i$ $(1 \leq i \leq n)$ such that

$$
\sum_{i=1}^{n-1} \|a_i - a_n\| < \gamma(A_1,\cdots,A_n) + \varepsilon.
$$

Improving the extremal principles by Mordukhovich et.al., the author [29] established the following result.

**Theorem A.** Consider closed sets $A_1,\cdots,A_n$ of a Banach (resp. Asplund) space $X$ such that $\bigcap_{i=1}^{n} A_i = \emptyset$. Let $\varepsilon > 0$ and $a_i \in A_i$ $(1 \leq i \leq n)$ satisfy (1.1). Then, for any $\lambda > 0$ there exist $\bar{a}_i \in A_i$ and $a_i^* \in X^*$ such that

1. $\sum_{i=1}^{n} \|\bar{a}_i - a_i\| < \lambda$, $\max_{1 \leq i \leq n-1} \|a_i^*\| = 1$ and $\sum_{i=1}^{n} a_i^* = 0$.
2. $a_i^* \in N_c(A_i,\bar{a}_i) + \frac{\varepsilon}{\lambda} B_{X^*}$ (resp. $a_i^* \in \hat{N}(A_i,\bar{a}_i) + \frac{\varepsilon}{\lambda} B_{X^*}$), $i = 1,\cdots,n$,

where $N_c(A_i,\bar{a}_i)$ and $\hat{N}(A_i,\bar{a}_i)$ denote respectively the Clarke and Fréchet normal cones (see Section 2 for their definitions).

Unfortunately, even in the case when $n = 2$, $A_1 = \{x\}$, and $A_2$ is convex (and closed) such that $x \notin A_2$, this theorem and all other existing fuzzy separation results cannot recapture the classical separation theorem stated at the beginning of this section. On the other hand, by the approximate projection theorem for a closed set (proved by the authors [30] and [12]) : for any $\eta \in (0,1)$, there exist $\bar{a}_2 \in A_2$ and $-a_2^* \in N_c(A_2,\bar{a}_2)$ such that $\|a_2^*\| = 1$ and

$$
\eta \|x - \bar{a}_2\| \leq \langle a_2^*,\bar{a}_2 - x \rangle.
$$

Clearly, (1.1) does imply that $A_1 = \{x\}$ and $A_2$ can be separated (in the usual sense) if $A_2$ is convex. From the theoretical viewpoint as well as for applications, it is important and interesting to have a new kind of fuzzy separation theorem which can result existing fuzzy separation theorems and classical convex separation results. It is one of our aims to establish such fuzzy separation results for closed sets.

Vector optimization relates to functional analysis and mathematical programming and has been found to play many important roles in economics theory, engineering design, management science and so on. In recent years, the study of vector optimization has received increasing attention in the literature (see books [7, 10, 13] and references therein). Another aim of this paper is to study constrained vector optimization problems, and thereby improve and extend some well-known results on numerical optimization. Many authors (cf. [14, 20, 23] and references therein) studied a numerical optimization problem with a constraint defined by finitely many inequalities and equalities. Most of the earlier authors provide necessary/sufficient conditions for a feasible point to be a solution, and their studies are based on the assumption that the
problem concerned does have a (local or global) solution. On one hand, this assumption is too restrictive in some context, while, on the other hand, we note a well known fact: if a function $\phi_0 : X \to \mathbb{R}$ is smooth and bounded below, then for any $\varepsilon > 0$ there exists $x_\varepsilon \in X$ such that

$$\phi_0(x_\varepsilon) < \inf_{x \in X} \phi_0(x) + \varepsilon \quad \text{and} \quad \|\phi_0'(x_\varepsilon)\| < \varepsilon. \quad \tag{1.3}$$

Without the smoothness assumption, in a geometric constraint case, Chou, Ng and Pang [4] proved the following result: if $\phi_0$ is Lipschitz and bounded below on a closed subset $A$ of $X$, then for any $\varepsilon > 0$ there exists $x_\varepsilon \in A$ such that

$$\phi(x_\varepsilon) < \inf_{x \in A} \phi_0(x) + \varepsilon \quad \text{and} \quad d(0, \partial \phi_0(x_\varepsilon) + N(\varepsilon)) < \varepsilon. \quad \tag{1.4}$$

Mordukhovich and Wang [18] studied suboptimality conditions for approximate solutions for a numerical constraint optimization problem in infinite dimension Asplund spaces. In particular, they established the Lagrange rule of an approximate solution for such a problem in terms of subdifferentials. With help of the separation theorem for finitely many closed sets, this and other related results as well as the result of Chou, Ng and Pang mentioned above are extended in Section 4 for vector optimization problems.

2. Preliminaries. For convenience of the readers, this section recalls some known notions and results in variational analysis, which will be used in our later analysis (see [14, 22,23] for more details).

We use $B_X$ and $\Sigma_X$ to denote the unit ball and unit sphere of $X$, respectively; and $B(x, r)$ denotes the open ball with center $a$ and radius $r$. Let $A$ be a closed subset of $X$ and $a$ be a point in $A$. We denote by $T_c(A, a)$ and $T(A, a)$ the Clarke tangent cone and the contingent (Bouligand) cone of $A$ at $a$, respectively, that is,

$$T_c(A, a) := \{v \in X : \forall a_n \overset{A}{\to} a \text{ and } \forall t_n \to 0^+ \exists v_n \to v \text{ s.t. } a_n + t_n v_n \in A \forall n \in \mathbb{N}\}$$

and

$$T(A, a) := \{v \in X : \exists t_n \to 0^+ \text{ and } v_n \to v \text{ s.t. } a + t_n v_n \in A \forall n \in \mathbb{N}\}.$$ 

The Clarke normal cone $N_c(A, a)$ of $A$ at $a$ is defined by

$$N_c(A, a) := \{x^* \in X^* \mid \langle x^*, h \rangle \leq 0 \text{ for all } h \in T_c(A, a)\}.$$ 

For $\varepsilon \geq 0$ and $a \in A$, the nonempty set

$$\hat{N}_\varepsilon(A, a) := \left\{x^* \in X^* \mid \limsup_{x \overset{A}{\to} a} \frac{\langle x^*, x - a \rangle}{\|x - a\|} \leq \varepsilon \right\}$$

is called the set of Fréchet $\varepsilon$-normals of $A$ at $a$, where $x \overset{A}{\to} a$ means $x \to a$ and $x \in A$. When $\varepsilon = 0$, $\hat{N}_\varepsilon(A, a)$ is a convex cone which is called the Fréchet normal cone of $A$ at $a$ and is denoted by $\hat{N}(A, a)$. The Mordukhovich (limiting) normal cone $N(A, a)$ of $A$ at $a$ is defined by

$$N(A, a) := \{x^* \in X^* : \exists x_n \to 0^+, a_n \overset{A}{\to} a \text{ and } x_n \overset{w^*}{\to} x^* \text{ s.t. } x_n^* \in \hat{N}_\varepsilon_n(A, a_n) \forall n \in \mathbb{N}\}. $$
It is known (cf. [14, 23]) that
\[ \hat{N}(A, a) \subset N(A, a) \subset N_c(A, a). \]

Mordukhovich and Shao [16] proved that if \( X \) is an Asplund space then
\[ N_c(A, a) = \text{cl}^* (\text{co}(N(A, a))) \quad \text{and} \quad N(A, a) = \limsup_{x \rightharpoonup a} \hat{N}(A, x), \]
where \( \text{cl}^* \) denotes the weak* closure. It is well known that if \( A \) is a convex set then
\[ T_c(A, a) = T(A, a) \quad \text{and} \quad N_c(A, a) = \hat{N}(A, a) = \{ x^* \in X^* | (x^*, x) \leq (x^*, a) \text{ for all } x \in A \}. \]

Let \( \phi : X \to \mathbb{R} \cup \{+\infty\} \) be a proper lower semicontinuous function. The Clarke-Rockafellar subdifferential \( \partial_c \phi(x) \) of \( \phi \) at \( x \in \text{dom}(\phi) \) is defined as
\[ \partial_c \phi(x) := \{ x^* \in X^* | (x^*, h) \leq \phi^1(x, h) \quad \forall h \in X \} \]
where
\[ \phi^1(x, h) := \limsup_{\varepsilon \downarrow 0} \liminf_{z \to x} \frac{\phi(z + tw) - \phi(z)}{t} \quad \forall h \in X. \]

The Fréchet subdifferential of \( \phi \) at \( x \in \text{dom}(\phi) \) is defined as
\[ \hat{\partial} \phi(x) := \{ x^* \in X^* | \liminf_{z \to x} \frac{\phi(z) - \phi(x) - (x^*, z - x)}{\|z - x\|} \geq 0 \}. \]

It is well known (cf. [14]) that
\[ (2.1) \quad \hat{\partial} \phi(x) \subset \partial_c \phi(x) \]
and that if \( \phi \) is convex then
\[ \partial_c \phi(x) = \hat{\partial} \phi(x) = \{ x^* \in X^* | (x^*, y - x) \leq \phi(y) - \phi(x) \quad \forall y \in X \} \quad \forall x \in \text{dom}(\phi). \]

For a closed set \( A \) in \( X \), let \( \delta_A \) denote the indicator function of \( A \). It is known (see [14, 23]) that
\[ N_c(A, a) = \partial_c \delta_A(a), \quad \hat{N}(A, a) = \hat{\partial} \delta_A(a) \quad \forall a \in A \]
and
\[ (\text{CS}) \quad \partial_c \phi(x) = \{ x^* \in X^* | (x^*, -1) \in N_c(\text{epi}(\phi), (x, \phi(x))) \} \quad \forall x \in \text{dom}(\phi), \]
\[ (\text{CF}) \quad \hat{\partial} \phi(x) = \{ x^* \in X^* | (x^*, -1) \in \hat{N}(\text{epi}(\phi), (x, \phi(x))) \} \quad \forall x \in \text{dom}(\phi) \]
where \( \text{epi}(\phi) := \{ (x, t) \in X \times \mathbb{R} : \phi(x) \leq t \} \).

We recall the following known subdifferential rules for sum-function (cf. [14, 22, 23]), which plays an important role in our later analysis.
Lemma 2.1. Let \( \phi_1, \phi_2 : X \to \mathbb{R} \cup \{+\infty\} \) be proper lower semicontinuous functions. Let \( x \in \text{dom}(\phi_1) \cap \text{dom}(\phi_2) \) and suppose that \( \phi_1 \) is locally Lipschitz around \( x \). Then,
\[
\partial_c(\phi_1 + \phi_2)(x) \subseteq \partial_c \phi_1(x) + \partial_c \phi_2(x).
\]
If, in addition, \( X \) is an Asplund space, then for any \( x^* \in \hat{\partial}(\phi_1 + \phi_2)(x) \) and any \( \varepsilon > 0 \) there exist \( x_1, x_2 \in B(x, \varepsilon) \) such that \( |\phi_1(x_i) - \phi_1(x)| < \varepsilon \) (\( i = 1, 2 \)) and
\[
x^* \in \hat{\partial} \phi_1(x_1) + \hat{\partial} \phi_2(x_2) + \varepsilon B_{X^*}.
\]

For a multifunction \( F \) between Banach spaces \( X \) and \( Y \), we use \( \text{Gr}(F) \) to denote its graph, and say that it is closed (resp. convex) if \( \text{Gr}(F) \) is a closed (resp. convex) subset of \( X \times Y \). Recall (cf. [2.9]) that \( F \) is pseudo-Lipschitz at \( (\bar{x}, \bar{y}) \in \text{Gr}(F) \) if there exist \( L, r_1, r_2 \in (0, +\infty) \) such that
\[
F(x_1) \cap B(\bar{y}, r_1) \subset F(x_2) + \|x_1 - x_2\|LB_Y \quad \text{for all } x_1, x_2 \in B(\bar{x}, r_2).
\]
For \( x \in X \) and \( y \in F(x) \), let \( \hat{D}^*F(x, y) \) and \( D^*_cF(x, y) : Y^* \rightrightarrows X^* \) denote the coderivatives of \( F \) at \( (x, y) \) with respect to the Fréchet and Clarke normal cones, respectively, that is,
\[
(2.2) \quad \hat{D}^*F(x, y)(y^*) := \{x^* \in X^* : (x^*, -y^*) \in \hat{N}(\text{Gr}(F), (x, y))\} \quad \text{for all } y^* \in Y^*,
\]
and
\[
D_c^*F(x, y)(y^*) := \{x^* \in X^* : (x^*, -y^*) \in N_c(\text{Gr}(F), (x, y))\} \quad \text{for all } y^* \in Y^*.
\]

3. Fuzzy separation results. In this section, we establish fuzzy separation results for finitely many closed sets, which not only unifies the convex separation theorem mentioned in Section 1 and the existing nonconvex separation results but also recaptures the approximate projection theorem proved in [30] and [12].

Let \( 1 \leq p \leq +\infty \) and \( \gamma_p(A_1, \ldots, A_n) \) denote the \( (p\text{-weighted}) \) non-intersect index of finitely many closed subsets \( A_1, \ldots, A_n \) of a Banach space \( X \), which is defined by
\[
\gamma_p(A_1, \ldots, A_n) := \inf \left\{ \left( \sum_{i=1}^{n-1} \left\| x_i - x_n \right\|^p \right)^{\frac{1}{p}} : x_i \in A_i, \quad i = 1, \ldots, n \right\}
\]
where \( \left( \sum_{i=1}^{n-1} \left\| x_i - x_n \right\|^p \right)^{\frac{1}{p}} \) is understood as \( \max_{0 \leq i \leq n} \left\| x_i - x_n \right\| \) when \( p = +\infty \).

For a point \( e \) and two subsets \( S_1 \) and \( S_2 \) of a Banach space, let
\[
d(S_1, S_2) := \inf\{\|u - v\| : u \in S_1 \text{ and } v \in S_2\} \quad \text{and} \quad d(e, S_2) := d(\{e\}, S_2).
\]

Theorem 3.1. Let \( A_1, \ldots, A_n \) be closed nonempty subsets of \( X \) be such that \( \bigcap_{i=1}^{n} A_i = \emptyset \). Let \( 1 \leq p, q \leq +\infty \) with \( \frac{1}{p} + \frac{1}{q} = 1 \), \( \varepsilon > 0 \) and \( a_i \in A_i \) (\( 1 \leq i \leq n \)) be such that
\[
(3.1) \quad \left( \sum_{i=1}^{n-1} \|a_i - a_n\|^p \right)^{\frac{1}{p}} < \gamma_p(A_1, \ldots, A_n) + \varepsilon.
\]
Then, for any \( \lambda > 0 \) there exist \( \bar{a}_i \in A_i \) and \( a_i^* \in X^* \) with the following properties:
(i) \( (\sum_{i=1}^{n} a_i^p) \alpha < \lambda \).

(ii) \( (\sum_{i=1}^{n} a_i^p) \beta = 1, \sum_{i=1}^{n} a_i = 0 \) and \( (\sum_{i=1}^{n} d(a_i, N_c(A_i, a_i)) \alpha < \zeta \).

(iii) \( (\sum_{i=1}^{n} \|a_n - a_i\| \beta = \sum_{i=1}^{n} (a_i, a_n - a_i). \)

Proof. Define \( \phi : X^n \to \mathbb{R} \cup \{+\infty\} \) as follows

\[
\phi(x_1, \cdots, x_n) := \left( \sum_{i=1}^{n-1} \|x_i - x_n\|^p \right)^\frac{1}{p} + \delta_{A_1 \times \cdots \times A_n}(x_1, \cdots, x_n)
\]

for all \((x_1, \cdots, x_n) \in X^n\), where \(X^n\) is equipped with the norm

\[
\|(x_1, \cdots, x_n)\| = \left( \sum_{i=1}^{n} \|x_i\|^p \right)^\frac{1}{p} \quad \forall (x_1, \cdots, x_n) \in X^n.
\]

Then

\[
\gamma_p(A_1, \cdots, A_n) = \inf \{ \phi(x_1, \cdots, x_n) : (x_1, \cdots, x_n) \in X^n \}
\]

and (by (3.1)) there exists \( \varepsilon' \in (0, \varepsilon) \) such that

\[
\phi(a_1, \cdots, a_n) < \inf \{ \phi(x_1, \cdots, x_n) : (x_1, \cdots, x_n) \in X^n \} + \varepsilon'.
\]

Since \( \phi \) is a lower semicontinuous function on the Banach space \( X^n \), it follows from the Ekeland variational principle (cf. [14, Theorem 2.26]) that there exists \((\bar{a}_1, \cdots, \bar{a}_n) \in X^n\) such that (i) holds and

\[
(\bar{a}_1, \cdots, \bar{a}_n) \leq \phi(x_1, \cdots, x_n) + \frac{\varepsilon'}{\lambda} \left( \sum_{i=1}^{n} \|x_i - \bar{a}_i\|^p \right)^\frac{1}{p} \quad \forall (x_1, \cdots, x_n) \in X^n.
\]

Hence \( \phi(\bar{a}_1, \cdots, \bar{a}_n) < +\infty \) and so \( \bar{a}_i \in A_i \) for each \( i \). Noting that \( \bigcap_{i=1}^{n} A_i = \emptyset \), it follows that

\[
(\bar{a}_1 - \bar{a}_n, \cdots, \bar{a}_{n-1} - \bar{a}_n) \neq (0, \cdots, 0).
\]

For each \((x_1, \cdots, x_n) \in X^n\), let

\[
f(x_1, \cdots, x_n) := \left( \sum_{i=1}^{n-1} \|x_i - x_n\|^p \right)^\frac{1}{p} + \frac{\varepsilon'}{\lambda} \left( \sum_{i=1}^{n} \|x_i - \bar{a}_i\|^p \right)^\frac{1}{p}.
\]

Then \( f \) is a continuous convex function on \( X^n \), and (3.2) means that \( f \) attains its minimum over \( A_1 \times \cdots \times A_n \) at \((\bar{a}_1, \cdots, \bar{a}_n)\). Hence \( 0 \in \partial f(\bar{a}_1, \cdots, \bar{a}_n) \times \cdots \times N_c(A_n, \bar{a}_n) \). This and Lemma 2.1 imply that

\[
0 \in \partial g(\bar{a}_1, \cdots, \bar{a}_n) + N_c(A_1, \bar{a}_1) \times \cdots \times N_c(A_n, \bar{a}_n) + \frac{\varepsilon'}{\lambda} B_{X^*},
\]
where \( g(x_1, \cdots , x_n) := \left( \sum_{i=1}^{n-1} \|x_i - x_n\|^p \right)^{\frac{1}{p}} \) for all \((x_1, \cdots , x_n) \in X^n\). Hence there exists \((-a_1^*, \cdots , -a_n^*) \in \partial g(\bar{a}_1, \cdots , \bar{a}_n)\) such that

\[
\left( \sum_{i=1}^{n} d(a_i^*, N_c(A_i, \bar{a}_i))^q \right)^{\frac{1}{q}} \leq \frac{\varepsilon'}{\lambda} < \frac{\varepsilon}{\lambda}.
\]

Thus,

\[
(3.4) \quad \sum_{i=1}^{n} \langle -a_i^*, x_i - \bar{a}_i \rangle \leq \left( \sum_{i=1}^{n-1} \|x_i - x_n\|^p \right)^{\frac{1}{p}} - \left( \sum_{i=1}^{n-1} \|\bar{a}_i - \bar{a}_n\|^p \right)^{\frac{1}{p}}
\]

for all \((x_1, \cdots , x_n) \in X^n\). Setting \(x_1 = \cdots = x_n = x\), it follows that

\[
\sum_{i=1}^{n} \langle -a_i^*, x - \bar{a}_i \rangle \leq - \left( \sum_{i=1}^{n-1} \|\bar{a}_i - \bar{a}_n\|^p \right)^{\frac{1}{p}} \quad \forall x \in X,
\]

and so \(\sum_{i=1}^{n} a_i^* = 0\). This and (3.4) imply that

\[
\sum_{i=1}^{n-1} \langle -a_i^*, x_i - x_n - (\bar{a}_i - \bar{a}_n) \rangle \leq \left( \sum_{i=1}^{n-1} \|x_i - x_n\|^p \right)^{\frac{1}{p}} - \left( \sum_{i=1}^{n-1} \|\bar{a}_i - \bar{a}_n\|^p \right)^{\frac{1}{p}}
\]

for all \((x_1, \cdots , x_n) \in X^n\). Taking an arbitrary element \((u_1, \cdots , u_{n-1})\) in \(X^{n-1}\) and letting \(x_i := u_i + x_n\) \((1 \leq i \leq n - 1)\), it follows that

\[
\sum_{i=1}^{n-1} \langle -a_i^*, u_i - (\bar{a}_i - \bar{a}_n) \rangle \leq \left( \sum_{i=1}^{n-1} \|u_i\|^p \right)^{\frac{1}{p}} - \left( \sum_{i=1}^{n-1} \|\bar{a}_i - \bar{a}_n\|^p \right)^{\frac{1}{p}}
\]

and so

\[
(-a_1^*, \cdots , -a_{n-1}^*) \in \partial \|_{X^{n-1}} (\bar{a}_1 - \bar{a}_n, \cdots , \bar{a}_{n-1} - \bar{a}_n).
\]

It follows from (3.3) that

\[
\left( \sum_{i=1}^{n-1} \|a_i - a_n\|^q \right)^{\frac{1}{q}} = 1 \quad \text{and} \quad \sum_{i=1}^{n-1} (a_i^*, \bar{a}_n - \bar{a}_i) = \left( \sum_{i=1}^{n-1} \|\bar{a}_i - \bar{a}_n\|^p \right)^{\frac{1}{p}}.
\]

This completes the proof. \(\Box\)

**Theorem 3.1'** Let \(A_1, \cdots , A_n\), and \(p,q\) be as in Theorem 3.1. Suppose that

\[
\left( \sum_{i=1}^{n-1} \|a_i - a_n\|^p \right)^{\frac{1}{p}} = \gamma_p(A_1, \cdots , A_n).
\]

Then, there exist \(a_i^* \in X^*\) \((1 \leq i \leq n)\) with the following properties:

- (i) \(\left( \sum_{i=1}^{n-1} \|a_i^*\|^q \right)^{\frac{1}{q}} = 1\), \(\sum_{i=1}^{n-1} a_i^* = 0\) and \(a_i^* \in N_c(A_i, a_i)\) \(i = 1, \cdots , n\).
- (ii) \(\left( \sum_{i=1}^{n} \|a_n - a_i\|^p \right)^{\frac{1}{p}} = \sum_{i=1}^{n-1} (a_i^*, a_n - a_i)\).
Proof. Let $\phi$ and $g$ be as in the proof of Theorem 3.1. Then
\[ \phi(a_1, \cdots, a_n) = \inf \{ \phi(x_1, \cdots, x_n) : (x_1, \cdots, x_n) \in X^n \}. \]
Hence
\[ 0 \in \partial \phi(a_1, \cdots, a_n) \subset \partial g(a_1, \cdots, a_n) + N_c(A_1, a_1) \times \cdots \times N_c(A_n, a_n). \]
It follows that $(a^*_1, \cdots, a^*_n) \in \partial g(x_1, \cdots, x_n)$ such that $a^*_i \in N_c(A_i, a_i) \text{ } (i = 1, \cdots, m)$. Noting that $(a_1 - a_n, \cdots, a_{n-1} - a_n) \neq (0, \cdots, 0)$, as in the corresponding part of the proof of Theorem 3.1, one has
\[ \left( \sum_{i=1}^{n-1} ||a^*_i||^q \right)^{\frac{1}{q}} = 1 \text{ and } \sum_{i=1}^{n-1} (a^*_i, a_i - a_n) = \left( \sum_{i=1}^{n-1} ||a_i - a_n||^p \right)^{\frac{1}{p}}. \]
The proof is completed. \( \Box \)

In view of Theorem 3.1, we have the following corollary.

Corollary 3.2. Let $A_1$ and $A_2$ be two closed nonempty subsets of $X$ such that $A_1 \cap A_2 = \emptyset$. Then, for any $\varepsilon > 0$ there exist $a_i \in A_i \text{ } (i = 1, 2)$ and $a^* \in X^*$ with $\|a^*\| = 1$ such that
\[ -a^* \in N_c(A_1, a_1) + \varepsilon B_{X^*}, \quad a^* \in N_c(A_2, a_2) + \varepsilon B_{X^*}, \]
and
\[ \|a_1 - a_2\| = \langle a^*, a_1 - a_2 \rangle < d(A_1, A_2) + \varepsilon. \]

Remark. In Corollary 3.2, $\varepsilon$ cannot be taken as 0 even in the convex setting. Indeed, there exist two closed convex sets $A_1$ and $A_2$ of $\mathbb{R}^2$ such that $d(A_1, A_2) > 0$ but $N(A_1, a_1) \cap -N(A_2, a_2) = \{0\}$ for any $a_1 \in A_1$ and $a_2 \in A_2$. Let $A_1 = \{(s, t) \in \mathbb{R}_+^2 \setminus \{0\} : \frac{1}{t} \leq s \}$ and $A_2 = \mathbb{R} \times [-1, -\infty)$. Then $A_1$ and $A_2$ are closed convex sets. It is clear that $\text{bd}(A_1) = \{(s, t) \in \mathbb{R}_+^2 \setminus \{0\} : t = \frac{1}{s}\}$, $\text{bd}(A_2) = \mathbb{R} \times \{-1\}$ and $\mathbb{R} \times \{0\}$ is the asymptotic line of $\text{bd}(A_1)$. Hence, $d(A_1, A_2) = 1$,
\[ N(A_1, (s, t)) = \mathbb{R}_+(-\frac{1}{s^2}, -1) \quad \text{and} \quad N(A_2, (s', t')) = \mathbb{R}_+(0, 1) \]
for all $(s, t) \in \text{bd}(A_1)$ and all $(s', t') \in \text{bd}(A_2)$. It follows that $N(A_1, (s, t)) \cap -N(A_2, (s', t')) = \{(0, 0)\}$ \( \forall (s, t) \in A_1 \text{ and } \forall (s', t') \in A_2 \).

Corollary 3.3. Let $A_1$ be a closed nonempty subset of $X$ and $A_2$ a closed, bounded and convex nonempty subset of $X$. Suppose that $A_1 \cap A_2 = \emptyset$. Then, for any $\varepsilon > 0$ there exist $a_1 \in A_1$ and $a^* \in N_c(A_1, a_1)$ with $\|a^*\| = 1$ such that
\[ d(A_1, A_2) - \varepsilon < \inf_{x \in A_2} \langle a^*, x \rangle - \langle a^*, a_1 \rangle. \]
Consequently, if in addition $A_1$ is convex then
\[ d(A_1, A_2) - \varepsilon < \inf_{x \in A_2} \langle a^*, x \rangle - \max_{x \in A_1} \langle a^*, x \rangle. \]
Proof. Let $k$ be an arbitrary natural number and take $a_i(k) \in A_i$ such that

\begin{equation}
\|a_1(k) - a_2(k)\| < d(A_1, A_2) + \frac{1}{k^2},
\end{equation}

that is,

\begin{equation}
\|a_1(k) - a_2(k)\| < \gamma_1(A_1, A_2) + \frac{1}{k^2}.
\end{equation}

By Theorem 3.1, there exist $\bar{a}_i(k) \in A_i$ and $a_i^*(k) \in X^*$ such that

\begin{equation}
\|a_i^*(k)\| = 1, \quad a_i^*(k) + a_i^*(k) = 0, \quad a_i^*(k) \in N_c(A_i, \bar{a}_i(k)) + \frac{1}{k}B_{X^*}, \quad i = 1, 2,
\end{equation}

and

\begin{equation}
\|\bar{a}_1(k) - \bar{a}_2(k)\| = \langle a_1^*(k), \bar{a}_2(k) - \bar{a}_1(k) \rangle.
\end{equation}

Take $\bar{a}_i^*(k) \in N_c(A_i, \bar{a}_i(k))$ such that $\|\bar{a}_i^*(k) - a_i^*(k)\| < \frac{1}{k}$ $(i = 1, 2)$. Then

\begin{equation}
1 - \frac{1}{k} < \|\bar{a}_i^*(k)\| < 1 + \frac{1}{k}, \quad \|\bar{a}_1^*(k) + \bar{a}_2^*(k)\| < \frac{2}{k}
\end{equation}

and so

\begin{align}
(1 - \frac{1}{k})\|\bar{a}_1(k) - \bar{a}_2(k)\| &\leq \langle \bar{a}_1^*(k), \bar{a}_2(k) - \bar{a}_1(k) \rangle \\
&\leq \langle -\bar{a}_2^*(k), \bar{a}_2(k) \rangle - \langle \bar{a}_1^*(k), \bar{a}_1(k) \rangle + \|\bar{a}_1^*(k) + \bar{a}_2^*(k)\|\|\bar{a}_2(k)\|
\end{align}

\begin{align}
&\leq - \max_{x \in A_2} \langle \bar{a}_2^*(k), x \rangle - \langle \bar{a}_1^*(k), \bar{a}_1(k) \rangle + \frac{2L}{k} \\
&\leq \inf_{x \in A_2} \langle \bar{a}_1^*(k), x \rangle - \langle \bar{a}_1^*(k), \bar{a}_1(k) \rangle + \frac{3L}{k}
\end{align}

where $L = \max_{x \in A_2} \|x\|$. Let $\bar{a}^*(k) := \frac{\bar{a}_1^*(k)}{\|\bar{a}_1^*(k)\|}$. Then $\bar{a}^*(k) \in N_c(A_1, \bar{a}_1(k))$, and it follows that

\begin{equation}
\frac{(1 - \frac{1}{k})\|\bar{a}_1(k) - \bar{a}_2(k)\| - \frac{3L}{k}}{\|\bar{a}_1^*(k)\|} \leq \inf_{x \in A_2} \langle \bar{a}^*(k), x \rangle - \langle \bar{a}^*(k), \bar{a}_1(k) \rangle.
\end{equation}

By (3.5) and (3.6), one has

\begin{equation}
\frac{(1 - \frac{1}{k})\|\bar{a}_1(k) - \bar{a}_2(k)\| - \frac{3L}{k}}{\|\bar{a}_1^*(k)\|} \to d(A_1, A_2).
\end{equation}

Hence

\begin{equation}
d(A_1, A_2) - \varepsilon < \inf_{x \in A_2} \langle \bar{a}^*(k), x \rangle - \langle \bar{a}^*(k), \bar{a}_1(k) \rangle
\end{equation}
for all \( k \) sufficiently large. The proof is completed. \( \square \)

**Remark.** In Corollary 3.3, if \( A_2 \) is compact, then \( d(A_1, A_2) > 0 \); taking \( \varepsilon \) in \( (0, \ d(A_1, A_2)) \), one can see that Corollary 3.3 improves and generalizes the convex separation Theorem mentioned in Section 1.

The following theorem infers that, when \( X \) is an Asplund space, the Clarke normal cone in Theorem 3.1 can be replaced by the Fréchet normal cone provided that the equality in Theorem 3.1 (iii) is replaced with an inequality.

**Theorem 3.4.** Let \( X \) be an Asplund space and \( A_1, \cdots, A_n \) be closed nonempty subsets of \( X \) such that \( \bigcap_{i=1}^{n} A_i = \emptyset \). Let \( 1 \leq p, q \leq +\infty \) with \( \frac{1}{p} + \frac{1}{q} = 1 \), \( \varepsilon > 0 \) and \( a_i \in A_i \ \ (1 \leq i \leq n) \) be such that

\[
\left( \sum_{i=1}^{n-1} \|a_i - a_n\|^p \right)^{\frac{1}{p}} < \gamma_p(A_1, \cdots, A_n) + \varepsilon.
\]

Then, for any \( \lambda > 0 \) and any \( \rho \in (0, 1) \) there exist \( \bar{a}_i \in A_i \) and \( a_i^* \in X^* \) with the following properties:

(i) \( \left( \sum_{i=1}^{n} \|\bar{a}_i - a_i\|^p \right)^{\frac{1}{p}} < \lambda \).

(ii) \( \left( \sum_{i=1}^{n} \|a_i^*\|^q \right)^{\frac{1}{q}} = 1, \sum_{i=1}^{n} a_i^* = 0 \) and \( \left( \sum_{i=1}^{n} d(a_i^*, N(A_i, \bar{a}_i)) \right)^{\frac{1}{q}} < \varepsilon \).

(iii) \( \rho \left( \sum_{i=1}^{n-1} \|\bar{a}_i - a_n\|^p \right)^{\frac{1}{p}} \leq \sum_{i=1}^{n-1} \langle a_i^*, \bar{a}_i - a_i \rangle \).

**Proof.** Let \( \phi \) be as in the proof of Theorem 3.1. Then

\[
\phi(a_1, \cdots, a_n) < \inf \{ \phi(x_1, \cdots, x_n) : (x_1, \cdots, x_n) \in X^n \} + \varepsilon.
\]

Take \( \varepsilon' \in (0, \varepsilon) \) and \( \lambda' \in (0, \lambda) \) such that

\[
\frac{\varepsilon'}{\lambda'} < \frac{\varepsilon}{\lambda} \quad \text{and} \quad \phi(a_1, \cdots, a_n) < \inf \{ \phi(x_1, \cdots, x_n) : (x_1, \cdots, x_n) \in X^n \} + \varepsilon'.
\]

It follows from Ekeland's variational principle that there exists \((\bar{a}_1, \cdots, \bar{a}_n) \in X^n\) such that

\[
\left( \sum_{i=1}^{n} \|\bar{a}_i - a_i\|^p \right)^{\frac{1}{p}} < \lambda'
\]

and

\[
\phi(\bar{a}_1, \cdots, \bar{a}_n) \leq \phi(x_1, \cdots, x_n) + \frac{\varepsilon'}{\lambda'} \left( \sum_{i=1}^{n} \|x_i - a_i\|^p \right)^{\frac{1}{p}} \forall (x_1, \cdots, x_n) \in X^n.
\]

Since \( \bigcap_{i=1}^{n} A_i = \emptyset \), (3.8) implies that

\[
\sum_{i=1}^{n-1} \|\bar{a}_i - a_n\| > 0.
\]
For each \((x_1, \ldots, x_n) \in X^n\), let
\[
f(x_1, \ldots, x_n) = \left( \sum_{i=1}^{n-1} \|x_i - x_n\|^p \right)^{\frac{1}{p}} + \frac{\epsilon'}{\lambda} \left( \sum_{i=1}^{n} \|x_i - \tilde{a}_i\|^p \right)^{\frac{1}{p}}.
\]

By \((3.8)\) and the definition of \(\phi\), one has \(0 \in \partial f + \delta_{A_1 \times \cdots \times A_n}(a_1, \ldots, \tilde{a}_n)\). Let \(0 < \beta < \min\{\frac{\epsilon}{\lambda}, \lambda'\}\). Then, by the Asplund space version of Lemma 2.1 and \((3.9)\), there exist \(\bar{x}_i \in X\) and \(\tilde{a}_i \in A_i\) such that
\[
\sum_{i=1}^{n} \|x_i - \tilde{a}_i\|^p < \beta, \quad \sum_{i=1}^{n} \|\tilde{a}_i - \bar{x}_i\|^p < \beta, \quad 0 < \sum_{i=1}^{n-1} \|\bar{x}_i - x_n\|.
\]

It follows from \((3.10)\) that \((i)\) holds. Let \(g\) be as in the proof of Theorem 3.1. Then, \(f = g + \frac{\epsilon'}{\lambda} \|\cdot\|_{X^n}\). By the convexity of \(f\) and \(g\), one has
\[
\partial f(x_1, \ldots, x_n) = \partial g(x_1, \ldots, x_n) + \frac{\epsilon'}{\lambda} B_{X^n}^\infty.
\]
It follows from \((3.11)\) that
\[
0 \in \partial g(x_1, \ldots, x_n) + \hat{N}(A_1, \tilde{a}_1) \times \cdots \times \hat{N}(A_n, \tilde{a}_n) + (\beta + \frac{\epsilon'}{\lambda}) B_{X^n}^\infty.
\]

Hence there exists \(-\{a_1^*, \ldots, a_n^*\} \in \partial g(x_1, \ldots, x_n)\) such that
\[
\left( \sum_{i=1}^{n} d(a_i^*, \hat{N}(A_i, \tilde{a}_i)) \right)^{\frac{1}{q}} \leq \beta + \frac{\epsilon'}{\lambda} < \frac{\epsilon}{\lambda}.
\]

Noting (by the third inequality of \((3.10)\)) that \((\bar{x}_1 - x_n, \ldots, \bar{x}_{n-1} - x_n) \neq (0, \cdots, 0)\), as in the corresponding part of the proof of Theorem 3.1, one has
\[
\sum_{i=1}^{n-1} \|a_i^*\|^q = 1 \quad \text{and} \quad \sum_{i=1}^{n-1} \langle a_i^*, \bar{x}_n - \bar{x}_i \rangle = \left( \sum_{i=1}^{n-1} \|\bar{x}_i - x_n\|^p \right)^{\frac{1}{p}}.
\]
It follows from \((3.10)\) that
\[
\sum_{i=1}^{n-1} \langle a_i^*, \bar{a}_n - \tilde{a}_i \rangle = \sum_{i=1}^{n-1} \langle a_i^*, \bar{x}_n - \bar{x}_i \rangle + \sum_{i=1}^{n-1} \langle a_i^*, \bar{a}_n - \bar{x}_n - (\tilde{a}_i - \bar{x}_i) \rangle
\]
\[
\geq \left( \sum_{i=1}^{n-1} \|\bar{x}_i - x_n\|^p \right)^{\frac{1}{p}} - \left( \sum_{i=1}^{n-1} \|\bar{a}_n - \bar{x}_n - (\tilde{a}_i - \bar{x}_i)\|^p \right)^{\frac{1}{p}}
\]
\[
\geq \left( \sum_{i=1}^{n-1} \|\tilde{a}_i - \bar{a}_n\|^p \right)^{\frac{1}{p}} - 2 \left( \sum_{i=1}^{n-1} \|\tilde{a}_n - \bar{x}_n - (\tilde{a}_i - \bar{x}_i)\|^p \right)^{\frac{1}{p}}
\]
\[
\geq \left( \sum_{i=1}^{n-1} \|\tilde{a}_i - \tilde{a}_n\|^p \right)^{\frac{1}{p}} - 2 \left( \sum_{i=1}^{n-1} (4\beta)^p \right)^{\frac{1}{p}}
\]
\[
\geq \left( \sum_{i=1}^{n-1} \|\tilde{a}_i - \tilde{a}_n\|^p \right)^{\frac{1}{p}} - 8(n-1)\beta.
\]
Note that β is arbitrary in \((0, \min\{\frac{\varepsilon}{\lambda}, \frac{\varepsilon'}{\lambda'}\})\) and that (3.10) and (3.9) imply that

\[
\lim_{\beta \to 0^+} \left( \sum_{i=1}^{n-1} \|\tilde{a}_i - \tilde{a}_n\|^\frac{1}{\rho} - 8(n-1)\beta \right) = \left( \sum_{i=1}^{n-1} \|\tilde{a}_i - \tilde{a}_n\|^\frac{1}{\rho} \right) > 0.
\]

By \(\rho \in (0, 1)\), one has

\[
\lim_{\beta \to 0^+} \rho \left( \sum_{i=1}^{n-1} \|\tilde{a}_i - \tilde{a}_n\|^\frac{1}{\rho} \right) = \rho \left( \sum_{i=1}^{n-1} \|\tilde{a}_i - \tilde{a}_n\|^\frac{1}{\rho} \right) < \rho \left( \sum_{i=1}^{n-1} \|\tilde{a}_i - \tilde{a}_n\|^\frac{1}{\rho} - 8(n-1)\beta \right).
\]

It follows that there exists \(\beta \in (0, \min\{\frac{\varepsilon}{\lambda}, \frac{\varepsilon'}{\lambda'}\})\) sufficiently small such that

\[
\rho \left( \sum_{i=1}^{n-1} \|\tilde{a}_i - \tilde{a}_n\|^\frac{1}{\rho} \right) < \left( \sum_{i=1}^{n-1} \|\tilde{a}_i - \tilde{a}_n\|^\frac{1}{\rho} \right) - 8(n-1)\beta.
\]

Consequently \(\rho \left( \sum_{i=1}^{n-1} \|\tilde{a}_i - \tilde{a}_n\|^\frac{1}{\rho} \right) < \sum_{i=1}^{n} \langle a_i^*, \tilde{a}_i - \tilde{a}_n \rangle\). The proof is completed. \(\Box\)

**Remark.** The extremal principle by Mordukhovich et al. plays a key role in variational analysis in infinite dimensional spaces and deals with finitely many closed set with a special common point (named as an extremal point). In contrast, Theorem A mentioned in Section 1 deals with finitely many closed sets whose intersection is empty. As observed in [29, p.1161, Remark], Theorem A improves the extremal principle. But, none of these fuzzy separation results can recapture the classical convex separation theorem even in the special case of a singleton set. We emphasize that the points \(\tilde{a}_i\) and \(a_i^*\) \((i = 1, 2, \ldots, n)\) in Theorem 3.1 (and Theorem 3.4) satisfy properties (i), (ii) and (iii) simultaneously: should only require these points only satisfy (i) and (ii) then the task is relatively easier and the contents of these theorems are basically the same as Theorem A but to require the points to have the additional property (iii) make the result even more interesting so as it not only covers the existing fuzzy separation results but also recaptures the classical convex separation theorem mentioned in Section 1. But, the existing fuzzy separation results cannot cover the convex separation theorem even in the special case of a singleton and a closed convex set.

In view of the above fuzzy separation theorem, we can establish approximate projection results as follows. In the special case when \(n = 1\), these approximate projection results have been known and played important role in the study of error bound, metric regularity and metric linear regularity for generalized equations (cf.[30,31]).

**Corollary 3.5.** Let \(X\) be an Asplund space and \(A_1, \ldots, A_n\) be closed nonempty subsets of \(X\). Let \(x \in X \setminus \bigcap_{i=1}^{n} A_i\) and \(\rho \in (0, 1)\). Then there exist \(a_i \in A_i\) and \(a_i^* \in X^* (1 \leq i \leq n)\) such that the following assertions hold:

(i) \(\max_{1 \leq i \leq n} \|a_i^*\| = 1\) and \(a_i^* \in \hat{N}(A_i, a_i) (1 \leq i \leq n)\).

(ii) \(\rho \sum_{i=1}^{n} \|x - a_i\| \leq \min \left\{ \sum_{i=1}^{n} d(x, A_i), \sum_{i=1}^{n} \langle a_i^*, x - a_i \rangle \right\}\).
Proof. For each natural number \( k \), take \( a_i(k) \in A_i \) (1 \( \leq i \leq n \)) such that

\[
\sum_{i=1}^{n} \|a_i(k) - x\| < \sum_{i=1}^{n} d(x, A_i) + \frac{1}{k^2}.
\]

Let \( A_{n+1} := \{x\} \). Then \( \gamma_1(A_1, \cdots, A_n, A_{n+1}) = \sum_{i=1}^{n} d(x, A_i) \) and

\[
\sum_{i=1}^{n} \|a_i(k) - x\| < \gamma_1(A_1, \cdots, A_n, A_{n+1}) + \frac{1}{k^2}.
\]

By Theorem 3.4 (applied to \( a_1 = a_1(k), \cdots, a_n = a_n(k), a_{n+1} = x, \varepsilon = \frac{1}{k^2}, \lambda = \frac{1}{k} \) and \( \rho = 1 - \frac{1}{k} \)), there exist \( \tilde{a}_i(k) \in A_i \) and \( a_i^*(k) \in X^* \) such that

\[
\sum_{i=1}^{n} \|\tilde{a}_i(k) - a_i(k)\| < \frac{1}{k},
\]

\[
\max_{1 \leq i \leq n} \|a_i^*(k)\| = 1, \quad a_i^*(k) \in \tilde{N}(A_i, \tilde{a}_i(k)) + \frac{1}{k} B_{X^*} \quad (1 \leq i \leq n)
\]

and

\[
(1 - \frac{1}{k}) \sum_{i=1}^{n} \|\tilde{a}_i(k) - x\| \leq \sum_{i=1}^{n} (a_i^*(k), x - \tilde{a}_i(k)).
\]

For each \( i \), take \( \tilde{a}_i^*(k) \in \tilde{N}(A_i, \tilde{a}_i(k)) \) such that \( \|\tilde{a}_i^*(k) - a_i^*(k)\| \leq \frac{1}{k} \), and let \( \eta_k := \max_{1 \leq i \leq n} \|\tilde{a}_i^*(k)\| \). It follows from (3.15) that

\[
\frac{1}{\eta_k}(1 - \frac{2}{k}) \sum_{i=1}^{n} \|\tilde{a}_i(k) - x\| \leq \sum_{i=1}^{n} \frac{\tilde{a}_i^*(k)}{\eta_k}, x - \tilde{a}_i(k).
\]

Clearly, (3.12) and (3.13) imply that

\[
\sum_{i=1}^{n} \|\tilde{a}_i(k) - x\| \leq \sum_{i=1}^{n} d(x, A_i) + \frac{1}{k} + \frac{1}{k^2}.
\]

Noting that \( \eta_k \to 1 \) as \( k \to \infty \), \( \rho \in (0, 1) \) and \( 0 < \sum_{i=1}^{n} d(x, A_i) \leq \sum_{i=1}^{n} \|a_i(k) - x\| \) for all \( k \), it follows from (3.16) that

\[
\rho \sum_{i=1}^{n} \|a_i(k) - x\| \leq \min \left\{ \sum_{i=1}^{n} d(x, A_i), \sum_{i=1}^{n} \left( \frac{a_i^*(k)}{\eta_k}, x - \tilde{a}_i(k) \right) \right\}
\]

for all \( k \) sufficiently large. The proof is completed. \( \Box \)

Similar to the proof of Corollary 3.5 (with Theorem 3.1 replacing Theorem 3.4), one can prove the following result.

**Corollary 3.6.** Let \( X \) be a general Banach space and \( A_1, \cdots, A_n \) be closed nonempty subsets of \( X \). Let \( x \in X \setminus \bigcap_{i=1}^{n} A_i \) and \( \rho \in (0, 1) \). Then there exist \( a_i \in A_i \) and \( a_i^* \in X^* (1 \leq i \leq n) \) such that the following assertions hold:
Theorems 3.1 and 3.4 unify the classical convex separation theorem and existing fuzzy separation results mentioned in Section 1.

4. Application to multiobjective optimization. Let $Y$ be a Banach space and $K$ be a closed convex pointed cone in $Y$, which specifies a partial order $\leq_K$ on $Y$ as follows: for $y_1, y_2 \in Y$,

$$y_1 \leq_K y_2 \text{ if and only if } y_2 - y_1 \in K.$$ 

Let $K^+$ denote the dual cone of $K$, that is,

$$K^+ := \{ y^* \in Y^* : 0 \leq \langle y^*, y \rangle \ \forall y \in K \}.$$ 

Let $Z$ be a subset of $Y$ and recall that $y \in Z$ is said to be a Pareto efficient point, written as $y \in \text{E}(Z, K)$, if $z \in Z$ and $z \leq_K y \implies z = y$. It is known and easy to verify that $y \in \text{E}(Z, K) \iff (Z + K) \cap (y - K) = \{ y \}$.

In the case when $\text{int}(K) \neq \emptyset$, recall that $y \in Z$ is said to be a weak Pareto efficient point, written as $y \in \text{WE}(Z, K)$, if

$$(Z + K) \cap (y - \text{int}(K)) = \emptyset.$$

Throughout this section, let $X$, $Y_0, Y_1, \ldots, Y_m$ be Banach spaces, $\Phi_i : X \Rightarrow Y_i$ ($i = 0, 1, \ldots, m$) be closed multifunctions, $A$ be a closed subset of $X$ and let $K_i$ be a closed convex cone in $Y_i$ ($i = 0, 1, \ldots, m$). We consider the following constraint vector optimization problem

$$K_0 - \min \Phi_0(x)$$

$$\Phi_i(x) \cap -K_i \neq \emptyset, \ i = 1, \ldots, m$$

$$x \in A.$$

In the special case when $Y_0 = \cdots = Y_m = \mathbb{R}$, $K_0 = \cdots = K_n = \mathbb{R}_+$, $K_n+1 = \cdots = K_m = \{0\}$ and each $\Phi_i$ is single-valued, (4.1) reduces to the usual constraint numerical optimization problem. In the remainder of this section, suppose that $K_0$ is pointed and let $Z$ denote the feasible set of (4.1), that is,

$$Z := A \cap \left( \bigcap_{i=1}^m \Phi_i^{-1}(-K_i) \right).$$

For $\bar{x} \in Z$ and $\bar{y} \in \Phi_0(\bar{x})$, we say that $(\bar{x}, \bar{y})$ is a Pareto solution (resp. weak Pareto solution) of vector optimization problem (4.1) if

$$\bar{y} \in \text{E}(\Phi_0(Z), K_0) \quad \text{(reps. } \bar{y} \in \text{WE}(\Phi_0(Z), K_0))$$

that is,

$$\Phi_0(Z) \cap (\bar{y} - K_0) = \{ \bar{y} \}$$
FUZZY SEPARATION THEOREM FOR FINITELY MANY CLOSED SETS

It is well known that

\[(\text{resp. } \Phi_0(Z) \cap (\bar{y} - \text{int}(K_0)) = \emptyset).\]

Many authors have established sufficient or necessary optimality conditions for Pareto solutions and weak Pareto solutions of constraint vector optimization (4.1) (see [3, 5, 6, 17, 21, 26–29, 32] and references therein). In general, even in the case when \(Y_0 = \cdots = Y_n, K_0 = \cdots = K_n = R_+\) and each \(\Phi_i\) is single-valued, (4.1) need not have a (Pareto or weak Pareto) solution if \(X\) is infinite dimensional. So it is natural and interesting to consider some kinds of approximate solutions. Let \(\Phi_0 : X \to R \cup \{+\infty\}\) be a proper lower semicontinuous function bounded below on \(Z\). For \(\varepsilon > 0\), one naturally define that \(\bar{x} \in Z\) is an \(\varepsilon\)-approximate solution of the following problem

\[(\text{NOP}) \quad \min_{x \in Z} \Phi_0(x)\]

if

\[\Phi_0(\bar{x}) < \inf\{\Phi_0(x) : x \in Z\} + \varepsilon,\]

or equivalently,

\[\text{diam}((\Phi_0(Z) + R_+) \cap (\bar{y}_0 - K_0)) < \varepsilon.\]

Motivated by (4.3) and (4.4), we introduce the following notions of approximate Pareto solution for vector optimization problem (4.1).

**DEFINITION 4.1.** Let \(\varepsilon > 0, \bar{x} \in Z\) and \(\bar{y}_0 \in \Phi_0(\bar{x})\). We say that \((\bar{x}, \bar{y}_0)\) is

(i) a \(\varepsilon\)-Pareto solution of (4.1) if

\[\text{diam}(\Phi_0(Z) + K_0) \cap (\bar{y}_0 - K_0)) < \varepsilon\]

(ii) a weak \(\varepsilon\)-Pareto solution of (4.1) if there exists \(e \in \varepsilon B_{Y_0}\) such that

\[\Phi_0(Z) \cap (\bar{y}_0 + e - K_0) = \emptyset\]

(regardless \(\text{int}(K_0)\) is empty or not).

**PROPOSITION 4.1.** Let \(\varepsilon > 0, \bar{x} \in Z\) and \(\bar{y}_0 \in \Phi_0(\bar{x})\) be such that \((\bar{x}, \bar{y}_0)\) is a \(\varepsilon\)-Pareto solution of (4.1). Then, (4.6) holds for any \(e \in -K_0\) with \(\|e\| \geq \varepsilon\). Consequently, \((\bar{x}, \bar{y}_0)\) is a weak \(\varepsilon\)-Pareto solution of (4.1).

**Proof.** Take an arbitrary \(e \in -K_0\) with \(\|e\| \geq \varepsilon\). Noting that \(\bar{y}_0 \in (\Phi_0(Z) + K_0) \cap (\bar{y}_0 - K_0)\) and \(\|\bar{y}_0 - (\bar{y}_0 + e)\| = \|e\| \geq \varepsilon\), (4.5) implies that \(\bar{y}_0 + e \notin (\Phi_0(Z) + K_0) \cap (\bar{y}_0 - K_0)\) and so

\[(\Phi_0(Z) + K_0) \cap (\bar{y}_0 + e - K_0) = \emptyset.\]

This shows that \((\bar{x}, \bar{y}_0)\) is a weak \(\varepsilon\)-Pareto solution of (4.1).

By Definition 4.1, it is clear that if \((\bar{x}, \bar{y}_0)\) is a Pareto solution of (4.1) then \((\bar{x}, \bar{y}_0)\) is a \(\varepsilon\)-Pareto solution of (4.1) for any \(\varepsilon > 0\). In the case when \(\text{int}(K_0) \neq \emptyset\), noting that
of (4.1) for any $\varepsilon > 0$. The following example shows that $(\bar{x}, \bar{y}_0)$ is not necessarily a $\varepsilon$-Pareto solution of (4.1) when $(\bar{x}, \bar{y}_0)$ is a weak Pareto solution of (4.1).

**Example.** Let $X = Y = \cdots = Y_m = \mathbb{R}^2$, $K_1 = \cdots = K_m = \mathbb{R}^2$, $K_0 = \mathbb{R}^2_+$, $A = \mathbb{R}^2$, $\Phi_1 = \cdots = \Phi_m = I_{\mathbb{R}^2}$ and

$$\Phi_0(s, t) = \{(s, 0)\} \quad \forall (s, t) \in \mathbb{R}^2.$$ 

Then, $Z = \mathbb{R}^2$ and $\Phi_0(Z) + K_0 = \mathbb{R} \times \mathbb{R}^+$. Let $(s, t) \in Z$. It is easy to verify that $((s, t), (s, 0))$ is a weak Pareto solution of (4.1) and

$$(\Phi_0(Z) + K_0) \cap ((s, 0) - K_0) = (-\infty, s] \times \{0\},$$

and so $\text{diam}((\Phi_0(Z) + K_0) \cap ((s, 0) - K_0)) = +\infty$. Hence $((s, t), (s, 0))$ is not a $\varepsilon$-Pareto solution of (4.1) for any $\varepsilon > 0$.

Given a fixed $K_0 \in K_0 \setminus \{0\}$, in 1979, Kutateladze introduced the concept of $(\varepsilon, K_0)$-minimizer of $\Phi_0(Z)$ with respect to $K_0$: $\bar{y}_0 \in \Phi_0(Z)$ is said to be a $(\varepsilon, K_0)$-minimizer of $\Phi_0(Z)$ if (4.6) holds for $e = -\varepsilon K_0$. Kutateladze’s concept is a very popular kind of $\varepsilon$-solutions in vector optimization (see [1,2] for the details). Several authors considered other kinds of $\varepsilon$-solutions for vector optimization (see [9,19,24,25]). Recently, Gutierrez, Jimenez and Novo [8] introduced a new $\varepsilon$-solution concept which extends many $\varepsilon$-solution notions introduced in the literature. Most of existing approximate solutions are weaker than the $\varepsilon$-Pareto solution and stronger than the weak $\varepsilon$-Pareto solution. We will provide some necessary conditions for the existence of weak $\varepsilon$-Pareto solutions and some sufficient conditions for the existence of $\varepsilon$-Pareto solutions.

It is trivial that if a real-valued function $\phi : X \to \mathbb{R}$ is bounded below over a subset $Z$ of $X$ then for any $\varepsilon > 0$ there exists $x_\varepsilon \in Z$ such that

$$(*) \quad \phi(x_\varepsilon) - \varepsilon < \phi(x) \quad \forall x \in Z.$$ 

It is natural to ask whether the corresponding result on $\varepsilon$-Pareto solutions for vector optimization is true. The following example says that the answer to this problem is negative.

**Example.** Let $X = \mathbb{R}$, $p \in [1, +\infty)$, $Y = \ell^p$ and $F : X \rightrightarrows Y$ be such that

$$F(x) = \left\{ \left( \frac{1}{|x| + 1}, 0, 0, \cdots \right) \right\} \quad \forall x \in X.$$ 

Then $F$ is a continuous single-valued function. Let $Z = X$ and $K_0$ consist of all $y = (t_1, t_2, \cdots) \in \ell^p$ such that $\sum_{k=1}^n t_k \geq 0$ for each $n \in \mathbb{N}$. It is clear that $K_0$ is a closed convex pointed cone in $Y$ and 0 is a below bound of $F$ over $Z$ with respect to $K_0$. Now we show that (4.1) has no $\varepsilon$-Pareto solution for any $\varepsilon > 0$. Indeed, let $\bar{x} \in X$, $\bar{u} = 2|\bar{x}| + 1$, $\bar{y} := \left( \frac{1}{|\bar{x}| + 1}, 0, 0, \cdots \right)$ and $\bar{z} := \left( \frac{1}{2(|\bar{x}| + 1)}, 0, 0, \cdots \right)$. Then $F(\bar{x}) = \{\bar{y}\}$ and $F(\bar{u}) = \{\bar{z}\}$. For any $n \in \mathbb{N}$, let $y_n := (0, s_1, \cdots, s_{2n}, 0, 0, \cdots)$ be such that $s_{2k-1} = -\frac{1}{4(|\bar{x}| + 1)}$ and $s_{2k} = \frac{1}{4(|\bar{x}| + 1)}$ $(k = 1, \cdots, n)$. It is easy to verify that $\bar{y} + y_n \in (\bar{z} + K_0) \cap (\bar{y} - K_0) \subset (F(Z) + K_0) \cap (\bar{y} - K_0) \quad \forall n \in \mathbb{N}$. 

Noting that \( \bar{y} \in (F(Z) + K_0) \cap (\bar{y} - K_0) \), it follows that
\[
\text{diam}(F(Z) + K_0) \cap (\bar{y} - K_0) \geq \|y_n\| = \frac{n}{2(|\bar{x}| + 1)} \to +\infty.
\]
This shows that \((\bar{x}, \bar{y})\) is not a \(\varepsilon\)-Pareto solution of (4.1) for any \(\varepsilon > 0\).

We will show that (4.1) always has a weak \(\varepsilon\)-Pareto solution if the objective multifunction \(\Phi_0\) is bounded below on the feasible set \(A\) with respect to \(K_0\). Moreover, under the mild assumption on the ordering cone, we can establish the same result for \(\varepsilon\)-Pareto solutions. To do this, recall that a closed convex cone \(K\) of a Banach space \(Y\) is said to have a bounded base if there exists a bounded closed convex subset \(\Theta\) of \(K\) such that
\[
(4.7) \quad 0 \notin \Theta \quad \text{and} \quad K = \{t\theta : t \geq 0 \text{ and } \theta \in \Theta\}.
\]
It is known that every closed convex pointed cone in a finite dimensional Banach space has a bounded base (cf. [11]).

**Proposition 4.2.** Let the objective multifunction \(\Phi_0\) be bounded below on the feasible set \(Z\) with respect to \(K_0\), that is, there exists \(b \in Y_0\) such that
\[
b \leq_{K_0} y \quad \forall y \in \Phi_0(Z).
\]
Then the following statements hold:

(i) For any \(\varepsilon > 0\), (4.1) always has a weak \(\varepsilon\)-Pareto solution.

(ii) If, in addition, \(K_0\) has a bounded base, then, for any \(\varepsilon > 0\), (4.1) has an \(\varepsilon\)-Pareto solution.

**Proof.** Note that \(K_0\) is pointed and \(K_0 \neq \{0\}\). Hence there exist \(y_0^* \in K_0^+\) and \(c_0 \in K_0\) such that \(\langle y_0^*, c_0 \rangle > 0\). Since \(\Phi_0\) is bounded below on \(Z\) with respect to \(K_0\), for any \(\varepsilon > 0\) there exist \(\bar{x} \in Z\) and \(\bar{y}_0 \in \Phi_0(\bar{x})\) such that
\[
\langle y_0^*, \bar{y}_0 \rangle < \inf_{y \in \Phi_0(Z)} \langle y_0^*, y \rangle + \langle y_0^*, \varepsilon c_0 \rangle.
\]
It follows that \(\Phi_0(Z) \cap (\bar{y}_0 - \frac{\varepsilon c_0}{\|c_0\|} - K_0) = \emptyset\). Hence \((\bar{x}, \bar{y}_0)\) is a weak \(\varepsilon\)-Pareto solution of (4.1). This shows that (i) holds.

To prove (ii), suppose that \(K_0\) has a bounded base. Hence there exists a bounded closed convex subset \(\Theta\) of \(K_0\) such that (4.7) holds. By the separation theorem, there exists \(y_0^* \in Y_0^*\) with \(\|y_0^*\| = 1\) such that
\[
(4.8) \quad \eta := \inf_{\theta \in \Theta} \langle y_0^*, \theta \rangle > 0.
\]
This and (4.7) imply that \(y_0^* \in K_0^+\). Since \(\Phi_0\) is bounded below on \(Z\) with respect to \(K_0\), \(y_0^*\) is bounded below on \(\Phi_0(Z)\) and hence is bounded below on \(\Phi_0(Z) + K_0\). Let \(\varepsilon\) be an arbitrary positive number and take \(\bar{x} \in Z\) and \(\bar{y}_0 \in \Phi_0(Z)\) such that
\[
(4.9) \quad \langle y_0^*, \bar{y}_0 \rangle - \frac{\varepsilon\eta}{2M} < \inf_{y \in \Phi_0(Z) + K_0} \langle y_0^*, y \rangle,
\]
where \(M = \sup_{\theta \in \Theta} \|\theta\|\). On the other hand, (4.8) implies that
\[
\langle y_0^*, \bar{y}_0 - t\theta \rangle \leq \langle y_0^*, \bar{y}_0 \rangle - \frac{\varepsilon\eta}{2M} \quad \forall (t, \theta) \in \left[\frac{\varepsilon}{2M}, +\infty\right) \times \Theta.
\]
It follows from (4.9) that \( \bar{y}_0 - t \theta \notin \Phi_0(Z) + K_0 \) for any \((t, \theta) \in \left[ \frac{\varepsilon}{2M}, +\infty \right) \times \Theta\), that is,

\[
(\Phi_0(Z) + K_0) \cap (\bar{y}_0 - K_0) \subset (0, \frac{\varepsilon}{2M}) \Theta.
\]

Hence \( \text{diam}(\Phi_0(Z) + K_0) \cap (\bar{y}_0 - K_0) \leq \frac{\varepsilon}{2} \). This shows that \( (\bar{x}, \bar{y}_0) \) is an \( \varepsilon \)-Pareto solution of (4.1). The proof is completed.

For various types of approximate solutions for (4.1), the following implications indicated in the diagram hold (" \( \Rightarrow \) " is under the assumption that \( \text{int}(K_0) \neq \emptyset \)):

\[
\begin{align*}
\text{Pareto} & \quad \Rightarrow \quad \varepsilon\text{-Pareto} \quad \Rightarrow \quad \text{weak } \varepsilon\text{-Pareto} \\
& \quad \Rightarrow \quad \text{weak-Pareto}
\end{align*}
\]

**Remark.** All “reverse implications” are not valid and “weak Pareto” does not imply “\( \varepsilon \)-Pareto”.

Let \( \phi : X \to \mathbb{R} \) be a real-valued Lipschitz function such that \( \phi \) is bounded below on \( Z \). It is well known (cf. [4]) that for any \( \varepsilon > 0 \) there exists \( a_\varepsilon \in A \) such that

\[
\phi(a_\varepsilon) < \inf_{x \in Z} \phi(x) + \varepsilon \quad \text{and} \quad d(0, \partial_{0}\phi(a_\varepsilon) + N_c(Z, a_\varepsilon)) < \varepsilon.
\]

In this section, based on fuzzy separations obtained in Section 3, we consider the corresponding issues for multiobjective optimization problem (4.1). To do this, we first provide the Lagrange-like multiplier rule for a weak \( \varepsilon \)-Pareto solution of (4.1).

**Theorem 4.3.** Let \( \varepsilon > 0 \) and \( (\bar{x}, \bar{y}_0) \) be a weak \( \varepsilon \)-Pareto solution of (4.1). Let \( \bar{y}_i \in \Phi_i(\bar{x}) \cap -K_i \) \( (i = 1, \ldots, m) \). Then, for any \( \lambda > 0 \) there exist \( x_i \in B(\bar{x}, \lambda), y_i \in \Phi_i(x_i) \cap B(\bar{y}_i, \lambda), x_{m+1} \in A \cap B(\bar{x}, \lambda), c_i^* \in K_i^+, \)

\[
x_i^* \in D^*_c \Phi_i(x_i, y_i)(c_i^* + \frac{\varepsilon}{\lambda} B_{Y_i}) + \frac{\varepsilon}{\lambda} B_X \quad (0 \leq i \leq m) \quad \text{and} \quad x_{m+1}^* \in N_c(A, x_{m+1}) + \frac{\varepsilon}{\lambda} B_X
\]

such that \( \sum_{i=0}^{m} x_i^* = 0 \) and

\[
(4.10) \quad \frac{1}{2} - \frac{\varepsilon}{\lambda} \leq \sum_{i=0}^{m} (\|x_i^*\| + \|c_i^*\|) < 1 + \frac{\varepsilon}{\lambda}
\]

**Proof.** Since \( (\bar{x}, \bar{y}_0) \) is a weak \( \varepsilon \)-Pareto solution of (4.1), there exists \( e \in Y_0 \) with \( \|e\| < \varepsilon \) such that (4.6) holds. Equip the product space \( X \times \prod_{i=0}^{m} Y_i \) with the following norm

\[
\|(x, y_0, \ldots, y_m)\| := \max \left\{ \|x\|, \max_{0 \leq i \leq m} \|y_i\| \right\} \quad \forall (x, y_0, \ldots, y_m) \in X \times \prod_{i=0}^{m} Y_i
\]
By the definition of each

\[ A_i := \left\{ (x, y_0, \cdots, y_m) \in X \times \prod_{i=0}^m Y_i : (x, y_i) \in \text{Gr}(\Phi_i) \right\} \quad (i = 0, 1, \cdots, m), \]

\[ A_{m+1} := A \times (\bar{y}_0 + e - K_0) \times \prod_{i=1}^m (\bar{y}_i - K_i). \]

We claim that \( \bigcap_{i=0}^{m+1} A_i = \emptyset \). To do this, suppose to the contrary that there exist \( \bar{x} \in A \) and \( \bar{y}_i \in \Phi_i(\bar{x}) \) \( (i = 0, 1, \cdots, m) \) such that

\[ \bar{y}_0 \in \bar{y}_0 + e - K_0 \quad \text{and} \quad \bar{y}_i \in \bar{y}_i - K_i \subseteq -K_i \quad (i = 1, \cdots, m). \]

It follows that \( \bar{x} \in A \cap \left( \bigcap_{i=1}^m \Phi_i^{-1}(-K_i) \right) = Z \) and so

\[ \bar{y}_0 \in \Phi_0(Z) \cap (\bar{y}_0 + e - K_0), \]

contradicting (4.6). This shows that \( \bigcap_{i=0}^{m+1} A_i = \emptyset \). Let

\[ a_0 = \cdots = a_m = (\bar{x}, \bar{y}_0, \bar{y}_1, \cdots, \bar{y}_m) \quad \text{and} \quad a_{m+1} = (\bar{x}, \bar{y}_0 + e, \bar{y}_1, \cdots, \bar{y}_m). \]

Then

\[ \max_{0 \leq i \leq m} \| a_i - a_{m+1} \| = \| e \| < \varepsilon \leq \gamma_{\infty}(A_0, A_1, \cdots, A_{m+1}) + \varepsilon. \]

By Theorem 3.1, there exist \( \bar{a}_i = (x_i, y_{i,0}, \cdots, y_{i,m}) \in A_i \) and \( (x_i^*, y_{i,0}^*, \cdots, y_{i,m}^*) \in (X \times Y_0 \times \cdots \times Y_{m+1})^* \) such that

\begin{equation}
\sum_{i=0}^{m+1} d(x_i^*, y_{i,0}^*, \cdots, y_{i,m}^*), N_c(A_i, \bar{a}_i) < \frac{\varepsilon}{\lambda},
\end{equation}

\begin{equation}
\max_{0 \leq i \leq m+1} \| \bar{a}_i - a_i \| = \max_{0 \leq i \leq m} \left\{ \max \left\{ \| x_i - \bar{x} \|, \max_{0 \leq k \leq m} \| y_{i,k} - \bar{y}_k \| \right\}, \right.
\end{equation}

\begin{equation}
\left. \max \left\{ \| x_{m+1} - \bar{x} \|, \| y_{m+1,0} - \bar{y}_0 - e \|, \max_{1 \leq k \leq m} \| y_{m+1,k} - \bar{y}_k \| \right\} < \lambda, \right.
\end{equation}

\begin{equation}
\sum_{i=0}^{m+1} \left( \| x_i^* \| + \sum_{k=0}^m \| y_{i,k}^* \| \right) = 1
\end{equation}

and

\begin{equation}
\sum_{i=0}^{m+1} (x_i^*, y_{i,0}^*, \cdots, y_{i,m}^*) = 0.
\end{equation}

By the definition of each \( A_i \), one has

\[ N_c(A_{m+1}, \bar{a}_{m+1}) \subset N_c(A, x_{m+1}) \times \prod_{i=0}^m K_i^+. \]
and
\[ N_c(A_i, \bar{a}_i) = \{(x^*, y^*_0, \ldots, y^*_m) : (x^*, y^*_i) \in N_c(\Phi_i, (x_i, y_i, i)) \text{ and } y^*_k = 0 \forall k \neq i\} \]
for \(0 \leq i \leq m\). This and (4.11) imply that there exist
\[(4.15) \quad (\tilde{x}_i^*, \tilde{y}_i^*) \in N_c(\Phi_i, (x_i, y_i, i)) \quad (0 \leq i \leq m),\]
\[(4.16) \quad \tilde{x}_{m+1}^* \in N_c(A, x_{m+1}) \quad \text{and} \quad (c_0^*, \cdots, c_m^*) \in \prod_{k=0}^m K_k^+\]
such that
\[(4.17) \quad \sum_{i=0}^{m+1} \|\tilde{x}_i^* - x_i^*\| + \sum_{i=0}^{m} \|\tilde{y}_i^* - y_i^*\| + \sum_{i,k=0, k \neq i}^m \|y_{i,k}^*\| + \sum_{k=0}^m \|y_{m+1,k}^* - c_k^*\| < \frac{\varepsilon}{\lambda}.\]

It follows from (4.14) that
\[ -\tilde{y}_k^* = c_k^* + (y_{m+1,k}^* - \tilde{y}_k^*) + \sum_{i=0, i \neq k}^m y_{i,k}^* \in c_k^* + \frac{\varepsilon}{\lambda} B_{Y^*}, \quad 0 \leq k \leq m.\]

By (4.14)—(4.17), one has
\[ x_k^* \in D^*_c \Phi_k(x_k, y_{k,k}) \left(c_k^* + \frac{\varepsilon}{\lambda} B_{Y^*}\right) + \frac{\varepsilon}{\lambda} B_{X^*} \quad k = 0, 1, \ldots, m,\]
\[ x_{m+1}^* \in N_c(A, x_{m+1}) + \frac{\varepsilon}{\lambda} B_{X^*} \quad \text{and} \quad \sum_{i=0}^{m+1} x_i^* = 0.\]

It remains to show (4.10). To do this, note from (4.14) that \(\sum_{i=0}^m x_i^* = -x_{m+1}^*\) and so
\[(4.18) \quad \sum_{i=0}^{m+1} \|x_i^*\| \leq 2 \sum_{i=0}^m \|x_i^*\|.\]

Similarly, by (4.14), one has
\[ -y_{k,k}^* = y_{m+1,k}^* + \sum_{i=0, i \neq k}^m y_{i,k}^* \quad \text{and so} \]
\[ \sum_{k=0}^m \|y_{k,k}^*\| \leq \sum_{k=0}^m \|y_{m+1,k}^*\| + \sum_{i,k=0, i \neq k}^m \|y_{i,k}^*\|;\]
hence
\[ \sum_{i=0}^{m+1} \sum_{k=0}^m \|y_{i,k}^*\| \leq \sum_{k=0}^m \|y_{m+1,k}^*\| + \sum_{i,k=0, i \neq k}^m \|y_{i,k}^*\| + \sum_{k=0}^m \|y_{k,k}^*\| \]
\[(4.19) \quad \leq 2 \left( \sum_{k=0}^m \|y_{m+1,k}^*\| + \sum_{i,k=0, i \neq k}^m \|y_{i,k}^*\| \right).\]
By adding up the estimates (4.18) and (4.19) and making use of (4.13), we have
\[
1 \leq 2 \left( \sum_{i=0}^{m} \|x_i^*\| + \sum_{k=0}^{m} \|y_{m+1,k}^*\| + \sum_{i,k=0,i\neq k}^{m} \|y_{i,k}^*\| \right)
\]
and so
\[
\frac{1}{2} \leq \sum_{i=0}^{m} (\|x_i^*\| + \|c_i^*\|) + \sum_{k=0}^{m} \|y_{m+1,k}^*\| + \sum_{i,k=0,i\neq k}^{m} \|y_{i,k}^* - c_i^*\|
\]
\[
< \sum_{i=0}^{m} (\|x_i^*\| + \|c_i^*\|) + \frac{\varepsilon}{\lambda}
\]
(see (4.17)). Thus the first inequality in (4.10) holds. Moreover, respectively by (4.13) and (4.17), note that
\[
\sum_{i=0}^{m} (\|x_i^*\| + \|y_{m+1,i}^*\|) \leq 1 \quad \text{and} \quad \sum_{i=0}^{m} \|c_i^* - y_{m+1,i}^*\| < \frac{\varepsilon}{\lambda}.
\]
Thus, by the triangle inequality, we also see that the second inequality in (4.10) holds. The proof is completed. \(\square\)

**Theorem 4.4.** Let \(\Phi_0\) be bounded below on the feasible set \(Z\) with respect to the ordering cone \(K_0\) and suppose that \(K_0\) has a bounded base. Then one of the following two assertions holds:

(i) For any \(\varepsilon > 0\) there exist \(\bar{x} \in Z\) and \(\bar{y}_0 \in \Phi_0(\bar{x})\) such that \((\bar{x}, \bar{y}_0)\) is a \(\varepsilon\)-Pareto solution of (4.1) and there exist \(x_0 \in B(\bar{x}, \varepsilon)\), \(y_0 \in \Phi_0(x_0) \cap B(\bar{y}_0, \varepsilon)\), \(x_i \in B(\bar{x}, \varepsilon)\) and \(y_i \in \Phi_i(x_i) \cap (-K_i + \varepsilon B_{Y_i}) (1 \leq i \leq m)\), \(a \in A \cap B(\bar{x}, \varepsilon)\) and \(c_i^* \in K_i^+\) satisfying the following properties:
\[
\sum_{i=0}^{m} \|c_i^*\| = 1 \quad \text{and} \quad 0 \in \sum_{i=0}^{m} D^*_c \Phi_i(x_i, y_i)(c_i^* + \varepsilon B_{Y_i^*}) + N_c(A, a) + \varepsilon B_{X^*}.
\]

(ii) For any \(\varepsilon > 0\) there exist \(\bar{x} \in Z\) and \(\bar{y}_0 \in \Phi_0(\bar{x})\) such that \((\bar{x}, \bar{y}_0)\) is a \(\varepsilon\)-Pareto solution of (4.1) and there exist \(x_0 \in B(\bar{x}, \varepsilon)\), \(y_0 \in \Phi_0(x_0) \cap B(\bar{y}_0, \varepsilon)\), \(x_i \in B(\bar{x}, \varepsilon)\) and \(y_i \in \Phi_i(x_i) \cap (-K_i + \varepsilon B_{Y_i}) (1 \leq i \leq m)\), \(a \in A \cap B(\bar{x}, \varepsilon)\),
\[
x_i^* \in D^*_c \Phi_i(x_i, y_i)(\varepsilon B_{Y_i^*}) \quad \text{and} \quad a^* \in N_c(A, a) + \varepsilon B_{X^*}
\]

satisfying the following properties:
\[
\sum_{i=0}^{m} x_i^* + a^* = 0 \quad \text{and} \quad \sum_{i=0}^{m} \|x_i^*\| + \|a^*\| = 1.
\]

**Proof.** By Proposition 4.2, for any \(n \in \mathbb{N}\) there exist \(\bar{x}_n \in Z\) and \(\bar{y}_n \in \Phi_0(\bar{x}_n)\) such that \((\bar{x}_n, \bar{y}_n)\) is a \(\frac{1}{n}\)-Pareto solution of (4.1). By Theorem 4.3 (applied to \(\varepsilon = \frac{1}{n}\) and \(\lambda = \frac{1}{n}\)), there exist \(x_0(n) \in B(\bar{x}_n, \frac{1}{n})\), \(y_0(n) \in \Phi_0(x_0(n)) \cap B(\bar{y}_n, \frac{1}{n})\), \(x_i(n) \in B(\bar{x}_n, \frac{1}{n})\) and \(y_i(n) \in \Phi_i(x_i(n)) \cap (-K_i + \frac{1}{n} B_{Y_i}) (1 \leq i \leq m)\), \(x_{m+1}(n) \in A \cap B(\bar{x}_n, \frac{1}{n})\), \(c_i^*(n) \in K_i^+\),
\[
(4.20) \quad x_i^*(n) \in D^*_c F(x_i(n), y_i(n))(c_i^*(n) + \frac{1}{n} B_{Y_i^*}) + \frac{1}{n} B_{X^*} \quad 0 \leq i \leq m
\]
and

\[(4.21)\quad x_{m+1}^*(n) \in N_c(A, x_{m+1}(n)) + \frac{1}{n} B_X.\]

such that

\[(4.22)\quad \sum_{i=0}^{m+1} x_i^*(n) = 0 \quad \text{and} \quad 1 + \frac{1}{n} > \max_{0 \leq i \leq m} \|x_i^*(n) + c_i^*(n)\| > \frac{1}{2} - \frac{1}{n}.\]

For each \(n \in \mathbb{N}\), let \(r_n := \sum_{i=0}^{m} \|c_i^*(n)\|\). We first consider the case when \(\{r_n\}\) is not convergent to 0. In this case, without loss of generality, we assume that \(r_n \geq r\) for some positive constant \(r\) and for all \(n \in \mathbb{N}\) (if necessary take a subsequence). Let \(\tilde{c}_i^*(n) := \frac{c_i^*(n)}{r_n}\). Then, \(\tilde{c}_i^*(n) \in K_i^+, \sum_{i=0}^{m} \|\tilde{c}_i^*(n)\| = 1\) and it follows from (4.20)—(4.22) that

\(0 \in \sum_{i=0}^{m} D_{\epsilon}F(x_i(n), y_i(n))(\tilde{c}_i^*(n) + \frac{1}{nr} B_{Y^*}) + N_c(A, x_{m+1}(n)) + \frac{m+2}{nr} B_X. \quad \forall n \in \mathbb{N}.

This implies that (i) holds. Now assume that \(r_n \to 0\). In this case, by (4.22), \(l_n := \sum_{i=0}^{m+1} \|x_i^*(n)\| \geq \frac{1}{n}\) for all \(n\) sufficiently large. It follows from (4.20)—(4.22) that

\[
\frac{x_i^*(n)}{l_n} \in D_{\epsilon}F(x_i(n), y_i(n))(\frac{r_n}{m_n} + \frac{1}{nl_n} B_{Y^*}) + \frac{1}{nl_n} B_X. \quad 0 \leq i \leq m,
\]

\[
\frac{x_{m+1}^*(n)}{l_n} \in N_c(A, x_{m+1}(n)) + \frac{1}{nl_n} B_X,
\]

\[
\sum_{i=0}^{m+1} \frac{x_i^*(n)}{l_n} = 0 \quad \text{and} \quad \sum_{i=0}^{m+1} \|x_i^*(n)\| = 1.
\]

This implies that (ii) holds. The proof is completed. \(\square\)

In the Asplund space case, similar to the proofs of Theorems 4.3 and 4.4, we can prove the following theorems 4.5 and 4.6 (but with Theorem 3.4 replacing Theorem 3.1).

**Theorem 4.5.** Let \(X, Y_0, \cdots, Y_m\) be Asplund spaces. Let \(\epsilon > 0\) and \((\bar{x}, \bar{y}_0)\) be a weak \(\epsilon\)-Pareto solution of (4.1). Let \(y_i \in \Phi_i(\bar{x}) \cap -K_i\ (i = 1, \cdots, m)\). Then, for any \(\lambda > 0\) there exist \(x_i \in B(\bar{x}, \lambda), y_i \in \Phi_i(x_i) \cap B(\bar{y}_i, \lambda), x_{m+1} \in A \cap B(\bar{x}, \lambda), c_i^* \in K_i^+, x_i^* \in \hat{D}^*\Phi_i(x_i, y_i)(c_i^* + \frac{\epsilon}{\lambda} B_{Y_i^*}) + \frac{\epsilon}{\lambda} B_{X^*}, 0 \leq i \leq m\) and \(x_{m+1}^* \in \hat{N}(A, x_{m+1}) + \frac{\epsilon}{\lambda} B_X^*\) such that

\[
\sum_{i=0}^{m+1} x_i^* = 0 \quad \text{and} \quad \frac{1}{2} - \frac{\epsilon}{\lambda} < \sum_{i=0}^{m} (\|x_i^*\| + \|c_i^*\|) < 1 + \frac{\epsilon}{\lambda}.
\]

**Theorem 4.6.** Let \(X, Y_0, \cdots, Y_m\) be Asplund spaces. Let \(\Phi_0\) be bounded below on the feasible set \(Z\) with respect to the ordering cone \(K_0\) and suppose that \(K_0\) has a bounded base. Then, one of the following two assertions holds:
(i) For any \( \varepsilon > 0 \) there exist \( \bar{x} \in Z \) and \( \bar{y}_0 \in \Phi_0(\bar{x}) \) such that \((\bar{x}, \bar{y}_0)\) is a \( \varepsilon \)-Pareto solution of (4.1) and there exist \( x_0 \in B(\bar{x}, \varepsilon) \), \( y_0 \in \Phi(x_0) \cap B(\bar{y}_0, \varepsilon) \), \( x_i \in B(\bar{x}, \varepsilon) \) and \( y_i \in \Phi(x_i) \cap (-K_i + \varepsilon B_Y) \) \((1 \leq i \leq m)\), \( a \in A \cap B(\bar{x}, \varepsilon) \) and \( c_i^* \in K_i^+ \) satisfying the following properties:

\[
\sum_{i=0}^{m} \|c_i^*\| = 1 \quad \text{and} \quad 0 \in \sum_{i=0}^{m} \tilde{D}^*\Phi_i(x_i, y_i)(c_i^* + \varepsilon B_{Y^*}) + \tilde{N}(A, a) + \varepsilon B_{X^*}.
\]

(ii) For any \( \varepsilon > 0 \) there exist \( \bar{x} \in Z \) and \( \bar{y}_0 \in \Phi_0(\bar{x}) \) such that \((\bar{x}, \bar{y}_0)\) is a \( \varepsilon \)-Pareto solution of (4.1) and there exist \( x_0 \in B(\bar{x}, \varepsilon) \), \( y_0 \in \Phi(x_0) \cap B(\bar{y}_0, \varepsilon) \), \( x_i \in B(\bar{x}, \varepsilon) \) and \( y_i \in \Phi(x_i) \cap (-K_i + \varepsilon B_Y) \) \((1 \leq i \leq m)\), \( a \in A \cap B(\bar{x}, \varepsilon) \),

\[x_i^* \in \tilde{D}^*\Phi_i(x_i, y_i)(\varepsilon B_{Y^*}) \quad \text{and} \quad a^* \in \tilde{N}(A, a) + \varepsilon B_{X^*},\]

satisfying the following properties:

\[
\sum_{i=0}^{m} x_i^* + a^* = 0 \quad \text{and} \quad \sum_{i=0}^{m} \|x_i^*\| + \|a^*\| = 1.
\]

Under the Lipschitz assumption, we have the following sharper result.

**Theorem 4.7.** Let \( X, Y_0, \ldots, Y_m \) be Asplund spaces and \( \Phi_0 \) be bounded below on the feasible set \( Z \) with respect to the ordering cone \( K_0 \). Suppose that \( K_0 \) has a bounded base and that each \( \Phi_i \) is Lipschitz. Then part (i) of Theorem 4.6 holds.

**Proof.** Let \( L > 0 \) be the Lipschitz constant of each \( \Phi_i \). Then, by [14, Theorem 3.2], one has

\[
(4.23) \quad \sup\{\|x^*\| : x^* \in \tilde{D}^*\Phi_i(x_i, y_i)(y_i^*)\} \leq L\|y_i^*\|
\]

for all \((x_i, y_i) \in \text{Gr}(\Phi_i)\) and \( y_i^* \in Y_i^* \). By Theorem 4.6, we need only show that Theorem 4.6 (ii) does not hold for \( \varepsilon \in (0, \frac{1}{3(m+1)L}) \). Let \( x_i \in X \), \( y_i \in \Phi_i(x_i) \), \( a \in A \), \( x_i^* \in \tilde{D}^*\Phi_i(x_i, y_i)(\frac{1}{3(m+1)L}B_{Y^*_i}) \) and \( a^* \in \tilde{N}_c(A, a) + \frac{1}{3(m+1)L}B_{X^*} \) satisfy that \( \sum_{i=0}^{m} x_i^* + a^* = 0 \). It suffices to show that \( \sum_{i=0}^{m} \|x_i^*\| + \|a^*\| \neq 1 \). By (4.23), one has \( \|x_0^*\| \leq L \frac{1}{3(m+1)L} = \frac{1}{3(m+1)} \). Hence \( \sum_{i=0}^{m} \|x_i^*\| \leq \frac{1}{3} \) and \( \|a^*\| = \| \sum_{i=0}^{m} x_i^* \| \leq \frac{1}{3} \). So \( \sum_{i=0}^{m} \|x_i^*\| + \|a^*\| \leq \frac{2}{3} \). This completes the proof. \( \square \)

**Remark.** Let \( f : X \to \mathbb{R} \cup \{+\infty\} \) be a proper lower semicontinuous function and define

\[F(x) = [f(x), +\infty) \quad \text{and} \quad G(x) = \{f(x)\} \quad \forall x \in X.\]

Recall (cf. [14,23]) that the following known properties:

(i) If \((x^*, -\lambda) \in \tilde{N}(\text{Gr}(F), (x, t)) \), then \( \lambda \geq 0 \).

(ii) If \( \lambda > 0 \) and \((x^*, -\lambda) \in \tilde{N}(\text{Gr}(F), (x, t)) \), then \( t = f(x) \) and \( \tilde{D}^*F(x, f(x))(\lambda) = \lambda \tilde{\partial}f(x) \).

(iii) For any \((x, t) \in \text{Gr}(F)\), \( \tilde{D}^*F(x, t)(0) = \tilde{D}^*F(x, f(x))(0) = \tilde{\partial}^\infty f(x) \).
(iv) If \( f \) is locally Lipschitz, then \( \partial^\infty f(x) = \{0\} \).

(v) For any \( \lambda \neq 0 \), \( \partial^* G(x, f(x))(\lambda) = \partial(\lambda f)(x) \).

(vi) \( \partial^* G(x, f(x))(0) = \partial^\infty f(x) \).

Let \( \phi_i : X \to \mathbb{R} \) be lower semicontinuous functions \((i = 0, 1, \ldots, m)\) and \( \Phi_i(x) = [\phi_i(x), +\infty) \) for \(0 \leq i \leq n\) and \( \Phi_i(x) = \{\phi_i(x)\} \) for \(n < i \leq m\). In the case when \( Y_0 = Y_1 = \cdots = Y_m = \mathbb{R}, K_0 = \cdots = K_n = \mathbb{R}_+ \) and \( K_{n+1} = \cdots = K_m = \{0\}\), (4.1) reduces to the usual numerical constraint optimization problem. Thus, in this special case, the coderivatives appearing in Theorems 4.6, 4.7 and 4.8 can be represented in terms of the Fréchet subdifferential of \( \Phi_i \); in particular, Theorem 4.8 recaptures Mordukhovich and Wang’s result mentioned in Section 1.

Remark. Let \( G : X \to 2^{Y_1 \times \cdots \times Y_m} \) be such that
\[
G(x) := \Phi_1(x) \times \cdots \times \Phi_m(x) \quad \forall x \in X
\]
and \( K := K_1 \times \cdots \times K_m \). Then vector optimization problem (4.1) can rewritten as
\[
\begin{align*}
K_0 - \min \Phi_0(x) \\
G(x) \cap -K \neq \emptyset \\
x \in A.
\end{align*}
\]

(4.24)

It is clear that the feasible set of (4.1) and the one of (4.24) are identical. Hence \((\tilde{x}, \tilde{y}_0)\) is a \(\varepsilon\)-Pareto solution (resp. a weak \(\varepsilon\)-Pareto solution) of (4.1) if and only if it is a \(\varepsilon\)-Pareto solution (resp. a weak \(\varepsilon\)-Pareto solution) of (4.24). Note that
\[
(*) \quad \sum_{i=1}^m \partial^* \Phi_i(x, y_i)(y_i^*) \subset \partial^* G(x, (y_1, \cdots, y_m))(y_1^*, \cdots, y_m^*)
\]
for any \( x \in X, y_i \in \Phi_i(x) \) and \( y_i^* \in Y_i^* \) \((i = 1, \cdots, m)\). But, even in the special case when \( \Phi_i(x) = [(\phi_i(x), +\infty)] \) for \(1 \leq i \leq n\) and \( \Phi_i(x) = \{\phi_i(x)\} \) for \(n < i \leq m\), one cannot establish the converse inclusion of \((*)\). As for the coderivatives with respect to the Clarke normal cones, the relationship between \( \sum_{i=1}^m \partial^c \Phi_i(x, y_i)(y_i^*) \) and \( \partial^c G(x, (y_1, \cdots, y_m))(y_1^*, \cdots, y_m^*) \) is more complicated; we don’t even known whether or not the following inclusion \((*)\) is true:
\[
(*)' \quad \sum_{i=1}^m \partial^c \Phi_i(x, y_i)(y_i^*) \subset \partial^c G(x, (y_1, \cdots, y_m))(y_1^*, \cdots, y_m^*).
\]

Hence, we cannot establish Theorems 4.4–4.8 in terms of the corresponding necessary or sufficient conditions for a weak \(\varepsilon\)-Pareto solution (or a \(\varepsilon\)-Pareto solution) of (4.24).

Unfortunately, Theorems 4.4–4.8 cannot cover Chou, Ng and Pang’s result mentioned in Section 1 (because the \(\varepsilon\)-minimizer of \( \phi \) over \( A \) appearing in their result is itself a “\(\varepsilon\)-critical point” of \( \phi \) over \( A \)). For the rest of this paper, let us consider the following problem (which is a special case of (4.1)):
\[
(4.25) \quad K_0 - \min \Phi_0(x) \text{ subject to } x \in A
\]
where \( \Phi_0 : X \to Y_0 \) is a single-valued function and \( A \) is a nonempty closed subset of \( X \). The absence of functional constraint would allow us to draw some stronger
conclusions and thereby extend the corresponding numerical result of Chou, Ng and Pang.

For $\varepsilon > 0$, we say that $\bar{x} \in A$ is a $\varepsilon$-Pareto solution of (4.25) if

$$\text{diam}((\Phi_0(A) + K_0) \cap (\Phi_0(\bar{x}) - K_0)) < \varepsilon.$$ 

Let $\text{epi}_{K_0}(\Phi_0)$ denote the epi-graph of $\Phi_0$ with respect to $K_0$ and be defined by

$$\text{epi}_{K_0} := \{(x, y) \in X \times Y_0 : y \in \Phi_0(x) + K_0\}.$$ 

Imitating subdifferential formula (SC) of a scalar-valued function, we adopt the following coderivative $D^*_c \Phi_0(x) : Y_0^* \rightrightarrows X^*$ defined by

$$D^*_c \Phi_0(x)(y^*) := \{x^* \in X^* : (x^*, -y^*) \in N_c(\text{epi}_{K_0}(\Phi_0), (x, \Phi_0(x)))\} \quad \forall y^* \in Y_0^*.$$ 

Noting that

$$T_c(\text{epi}_{K_0}(\Phi_0), (x, \Phi_0(x))) = T_c(\text{epi}_{K_0}(\Phi_0), (x, \Phi_0(x))) + \{0\} \times K_0,$$

it is easy to verify that

$$\text{dom}(D^*_c \Phi_0(x)) \subset K_0^+.$$ 

We will need the following lemma, which is of some interest by itself.

**Lemma 4.8.** Let $x \in X$ and $y^* \in K_0^+$. Suppose that $\Phi_0 : X \to Y_0$ be locally Lipschitz. Then

$$\partial_c(y^* \circ \Phi_0)(x) \subset D^*_c \Phi_0(x)(y^*).$$

**Proof.** The version holds trivially if $y^* = 0$. Next assume that $y^* \in K_0^+ \setminus \{0\}$. Then, there exists $c_0 \in K_0$ such that $\langle y^*, c_0 \rangle > 0$. Let

$$S := \{(u, (y^*, v)) : (u, v) \in T_c(\text{epi}_{K_0}(\Phi_0), (x, \Phi_0(x)))\}.$$ 

By (CS), we only need to show that

$$S \subset T_c(y^* \circ \Phi_0)(x, (y^*, \Phi_0(x))).$$

To do this, let $(u, r) \in S$. Then there exists $v \in Y_0$ such that

$$(u, v) \in T_c(\text{epi}_{K_0}(\Phi_0), (x, \Phi_0(x))) \quad \text{and} \quad r = \langle y^*, v \rangle.$$ 

Consider any sequences $\{(x_n, t_n)\} \subset \text{epi}(y^* \circ \Phi_0)$ converging to $(x, (y^*, \Phi_0(x)))$ and $\{s_n\} \subset \mathbb{R}_+$ converging to 0. It is clear that $\{(x_n, t_n(x_n) + t_n \frac{t_n(y^* - \Phi_0(x_n))}{\langle y^*, c_0 \rangle} - c_0)\}$ is a sequence in $\text{epi}_{K_0}(\Phi_0)$ converging to $(x, \Phi_0(x))$. Hence there exists a sequence $\{(u_n, v_n)\}$ converging to $(u, v)$ such that

$$\left(x_n, \Phi_0(x_n) + t_n \frac{t_n(y^* - \Phi_0(x_n))}{\langle y^*, c_0 \rangle} - c_0\right) + s_n(u_n, v_n) \in \text{epi}_{K_0}(\Phi_0) \quad \forall n \in \mathbb{N}.$$
This implies that

\[(x_n, t_n) + s_n(u_n, \langle y^*, v_n \rangle) \in \text{epi}(y^* \circ \Phi_0) \quad \forall n \in \mathbb{N}.
\]

Since \((u_n, \langle y^*, v_n \rangle) \to (u, r)\), it follows that \((u, r) \in T_{\varepsilon}(\text{epi}(y^* \circ \Phi_0), (x, \langle y^*, \Phi_0(x) \rangle))\). This shows that (4.26) holds. \(\square\)

In the special case when \((Y_0, K_0) = (\mathbb{R}, \mathbb{R}_+)\), the following theorem recaptures Chou, Ng and Pang’s result. For the vector case, we need the condition that int\((K_0^+)\) is nonempty. This condition is equivalent to that \(K_0\) has a bounded base; in this case, \(\{c \in C : \langle y^*, c \rangle = 1\}\) is a bounded base of \(C\) for any \(y^* \in \text{int}(C^+)\).

**Theorem 4.9.** Let \(y^* \in \text{int}(K_0^+)\) and suppose that \(\Phi_0 : X \to Y_0\) is a locally Lipschitz function such that \(\Phi_0\) is bounded below on \(A\) with respect to \(K_0\). Then, for any \(\varepsilon > 0\), there exists \(x_\varepsilon \in A\) such that \(x_\varepsilon\) is an \(\varepsilon\)-Pareto solution of (4.25) and

\[
(4.27) \quad d(0, D^*_x\Phi_0(x_\varepsilon)(y^*) + N_c(A, x_\varepsilon)) < \varepsilon.
\]

**Proof.** Let \(\Theta := \{c \in K_0 : \langle y^*, c \rangle = 1\}\). Then \(\Theta\) is a bounded base of \(K_0\). Since \(\Phi_0\) is bounded below on \(A\) with respect to \(K_0\), \(y^* \circ \Phi_0\) is bounded below on \(A\). By Lemma 4.8 and Chou, Ng and Pang’s result, there exists \(x_\varepsilon \in A\) such that

\[
(4.28) \quad \langle y^*, \Phi_0(x_\varepsilon) \rangle < \inf_{x \in A} \langle y^*, \Phi_0(x) \rangle + \frac{\varepsilon}{M + 1}
\]

and (4.27) holds, where \(M := \sup_{\theta \in \Theta} \|\theta\|\). It remains to show that \(x_\varepsilon\) is a \(\varepsilon\)-Pareto solution of (4.25). We only need to show that

\[
(4.29) \quad (\Phi_0(A) + K_0) \cap (\Phi_0(x_\varepsilon) - K_0) \subset [-0, \frac{\varepsilon}{M + 1}]\Theta + \Phi_0(x_\varepsilon)
\]

(as \(\text{diam}([0, \frac{\varepsilon}{M + 1}]\Theta) < \varepsilon\)). To do this, let \(y = \Phi_0(x_\varepsilon) - t\theta \geq K_0 \Phi_0(a)\) for some \(t \in [0, +\infty), \theta \in \Theta\) and \(a \in A\). Since \(y^* \in \text{int}(K_0^+)\), it follows from (4.28) that

\[
t = \langle y^*, t\theta \rangle \leq \langle y^*, \Phi_0(x_\varepsilon) - \Phi_0(a) \rangle < \frac{\varepsilon}{M + 1}.
\]

Therefore (4.29) is shown. \(\square\)
