1. Introduction

Throughout the paper we assume that $\mu$ is a (Borel) probability measure on $\mathbb{R}^d$ with compact support. We call a family $E(\Lambda) = \{e^{2\pi i \lambda \cdot x} : \lambda \in \Lambda\}$ (where $\Lambda$ is a countable set) a Fourier frame of the Hilbert space $L^2(\mu)$ if there exist $A, B > 0$ such that

$$A\|f\|^2 \leq \sum_{\lambda \in \Lambda}|\langle f, e^{2\pi i \lambda \cdot x} \rangle|^2 \leq B\|f\|^2, \quad \forall f \in L^2(\mu).$$

(1.1)

Here the inner product is defined as usual,

$$\langle f, e^{2\pi i \lambda \cdot x} \rangle = \int_{\mathbb{R}^d} f(x)e^{-2\pi i \lambda \cdot x} d\mu(x).$$

$E(\Lambda)$ is called an exponential Riesz basis if it is both a basis and a frame of $L^2(\mu)$. Fourier frames and exponential Riesz bases are natural generalizations of exponential orthonormal bases in $L^2(\mu)$. They have fundamental importance in non-harmonic Fourier analysis and close connection with time-frequency analysis [2,8,9]. When (1.1) is satisfied, $f \in L^2(\mu)$ can be expressed as $f(x) = \sum_{\lambda \in \Lambda} c_\lambda e^{2\pi i \lambda \cdot x}$, and the expression is unique if it is a Riesz basis.

When $E(\Lambda)$ is an orthonormal basis (Riesz basis, or frame) of $L^2(\mu)$, we say that $\mu$ is a spectral measure (R-spectral measure) and $\Lambda$ is called a spectrum (R-spectrum). We will also use the term orthonormal spectrum instead of spectrum when we need to emphasize the orthonormal property. If $\mu$ is a spectral measure of $L^2(\mu)$, then $\Lambda$ is called a spectrum of $L^2(\mu)$.

E(Λ) only satisfies the upper bound condition in (1.1), then it is called a Bessel set (or Bessel sequence); for convenience, we also call A a Bessel set of $L^2(\mu)$.

One of the interesting and basic questions in non-harmonic Fourier analysis is:

What kind of compactly supported probability measures in $\mathbb{R}^d$ belong to the above classes of measures?

When $\mu$ is the restriction of the Lebesgue measure on $K$ with positive measure, the question whether it is a spectral measure is related to the well known Fuglede problem of translational tiles (see [7,22,14,26] and the reference therein). While it is easy to show that such $\mu$ is an $F$-measure, it is an open question whether it is an $R$-spectral measure. If $K$ is a unit interval, its $F$-spectrum was completely classified in terms of de Branges’s theory of entire functions [23]. In another general situation, Lai [13] proved a sharp result that if $\mu$ is absolutely continuous with respect to the Lebesgue measure, then it is an $F$-spectral measure if and only if its density function is essentially bounded above and below on the support.

The problem becomes more intriguing when $\mu$ is singular. The first example of such spectral measures was given by Jorgensen and Pedersen [11]. They showed that the Cantor measures with even contraction ratio ($\rho = 1/(2k + 1)$) is not. This raises the very interesting question on the existence of an exponential Riesz basis or a Fourier frame for such measures, and more generally for the self-similar measures [15,16,6,25,10]. In particular Dutkay et al. proposed to use the Beurling dimension as some general criteria for the existence of Fourier frame [4]. They also attempted to find a self-similar measure which admits an exponential Riesz basis or a Fourier frame but not an exponential orthonormal basis [5]. However, no such examples have been found up to now.

In this paper, we will carry out a detail study of the three classes of spectra mentioned. It is known that a spectral measure must be either purely discrete or purely continuous [16]. Our first theorem is a pure type law for the $F$-spectral measures.

**Theorem 1.1.** Let $\mu$ be an $F$-spectral measure on $\mathbb{R}^d$. Then it must be one of the three pure types: discrete (and finite), singularly continuous or absolutely continuous.

For the proof, the discrete case is based on the frame inequality, and the two continuous cases make use the concept of lower Beurling density of the $F$-spectrum.

To complete the previous digression on the continuous measures, we have the following conclusions for finite discrete measures.

**Theorem 1.2.** Let $\mu = \sum_{c \in C} p_c \delta_c$ be a discrete probability measure in $\mathbb{R}^d$ with $C$ a finite set. Then $\mu$ is an $R$-spectral measure.

To determine such discrete $\mu$ to be a spectral measure, we will restrict our consideration on $\mathbb{R}^1$ and let $C \subset \mathbb{Z}^+$ with $0 \in C$. Then the Fourier transform of $\mu$ is

$$\hat{\mu}(x) = p_0 + p_1 e^{2\pi i c_1 x} + \cdots + p_{k-1} e^{2\pi i c_{k-1} x} := m_\mu(x),$$

where $P = \{p_i\}_{i=1}^{k-1}$ is a set of probability weights. We call $m_\mu(x)$ the mask polynomial of $\mu$. Let $Z_\mu = \{x \in [0, 1]: m_\mu(x) = 0\}$ be the zero set of $m_\mu(x)$, and $\Lambda$ is called a bi-zero set if $\Lambda - \Lambda \subset Z_\mu \cup \{0\}$. Denote the cardinality of $E$ by $\#E$. It is easy to see the following simple proposition.

**Proposition 1.3.** Let $\mu = \sum_{c \in C} p_c \delta_c$ with $C \subset \mathbb{Z}^+$ and $0 \in C$. Then $\mu$ is a spectral measure if and only if there is a bi-zero set $\Lambda$ of $m_\mu$ and $\#\Lambda = \#C$. In this case, all the $p_c$ are equal.

The determination of the bi-zero set is, however, non-trivial, as the zeros of a mask polynomial is rather hard to handle. As an implementation of the proposition, we work out explicit expressions of the set $C$ and the bi-zero set when $\#C = 3, 4$. It is difficult to have such expression beyond 4 directly. On the other hand, there are systematic studies of the zeros of the mask polynomials by factorizing the mask polynomial as cyclotomic polynomials (the minimal polynomial of the root of unity). This has been used to study the integer tiles and their spectra (see [3,14,19]). We adopt this approach to a class of self-similar measures (which is continuous) in our consideration:

Let $n > 0$ and let $A \subset \mathbb{Z}^+$ be a finite set with $0 \in A$, we define a self-similar measure $\mu := \mu_{A,n}$ by

$$\mu(E) = \frac{1}{\#A} \sum_{a \in A} \mu(nE - a)$$

where $E$ is a Borel subset in $\mathbb{R}$. Note that the Lebesgue measure on $[0, 1]$ and the Cantor measures are such kind of measures. The following theorem is a combination of the results in [24,14] and [15]:

**Theorem 1.4.** Let $A \subset \mathbb{Z}^+$ be a finite set with $0 \in A$. Suppose there exists $B \subset \mathbb{Z}^+$ such that $A \otimes B = \mathbb{N}_n$, where $\mathbb{N}_n = \{0, \ldots, n - 1\}$. Then $\delta_A = \sum_{a \in A} \delta_a$ is a spectral measure with a spectrum in $\frac{1}{n} \mathbb{Z}$; the associated self-similar measure $\mu_{A,n}$ is also a spectral measure, and it has a spectrum in $\mathbb{Z}$ if $\gcd(A) = 1$. 

http://dx.doi.org/10.1016/j.acha.2012.05.003
Note that the $1/4$-Cantor measure $\mu_{[0,2]^4}$ satisfies the above condition, but not the $1/3$-Cantor measure. In fact, it is an open problem whether the $1/3$-Cantor measure is an F-spectral measure. To a lesser degree we want to know the existence of a singularly continuous measure that admits an R-spectrum but is not a spectral measure. Our final goal is to search for new R-spectral measures and to obtain such an example as corollary.

To this end, we let $\eta$ be a discrete probability measure with support $C \subset \mathbb{Z}^+$. Let $\nu$ be another probability measure on $\mathbb{R}$ with support $\Omega \subseteq [0, 1]$, and let $\mu = \eta \ast \nu$ be the convolution of $\eta$ and $\nu$. Our main result is

**Theorem 1.5.** Let $\mu = \eta \ast \nu$ be as the above, and assume that $\nu$ is an R-spectral measure with a spectrum in $\mathbb{Z}$. Then $\mu$ is an R-spectral measure.

In addition, if $Z_\nu \subseteq \mathbb{Z}$, then $\mu$ is a spectral measure if and only if both $\eta$ and $\nu$ are spectral measures.

We can modify the theorem slightly with the spectrum $\Gamma$ and $Z_\nu$ to be some subsets of rationals (Theorems 5.1, 5.3), this covers some more interesting cases (e.g., the Cantor measures). Finally by taking $\eta$ to be a non-uniform discrete measure (Proposition 1.3) and $\nu = \mu_{\Lambda,n}$ in Theorem 1.4, we conclude from Theorem 1.5 that

**Example 1.6.** There exists a singularly continuous measure which is an R-spectral measure, but not a spectral measure.

For the organization of the paper, we prove Theorem 1.1 in Section 2 and Theorem 1.2 in Section 3. We then deal with the discrete spectral measures in Section 3; Proposition 1.3 is proved, and explicit expressions of the measures. In the seminal paper [17], Landau gave an elegant and useful necessary condition for Beurling density and the types of the measures.

If $p > 0$, we have for all $f \in L^2(\mu),$

$$\sum_{x \in A} \left| \sum_{c \in C} f(c) e^{2\pi i \langle \lambda, c \rangle} p_c \right|^2 \leq B \sum_{c \in C} |f(c)|^2 p_c .$$

Taking $f = \delta_{p_0}$, where $p_0 > 0$, we have $(\# A) \cdot p_0^2 \leq B p_0$. Hence $\# A \leq B / p_0 < \infty$. This implies $\# C < \infty$ by the completeness of Fourier frame.

(ii) Suppose on the contrary that $D^{-} \Lambda \geq 0$. We claim that $\mathbb{Z}^d$ is a Bessel set of $L^2(\mu)$. By the definition of $D^{-} \Lambda$, we can choose a large $h \in \mathbb{N}$ such that

$$\inf_{x \in \mathbb{R}^d} \left| \# \left( \Lambda \cap Q_h(x) \right) \right| \geq c h^d > 1 .$$

Taking $x = h \mathbf{n}$, where $\mathbf{n} \in \mathbb{Z}^d$, we see that all cubes of the form $h \mathbf{n} + [-h/2, h/2]^d$ contains at least one points of $\Lambda$, say $\lambda_n$. Since $\Lambda$ is an F-spectrum, $\{\lambda_n \}_{n \in \mathbb{Z}^d}$ is a Bessel set. By the stability under perturbation (see e.g., [4, Proposition 2.3]) and $|\lambda_n - h \mathbf{n}| \leq \text{diam}([-h/2, h/2]^d) = \sqrt{d} h$,

Please cite this article in press as: X.-G. He et al., Exponential spectra in $L^2(\mu)$, Appl. Comput. Harmon. Anal. (2012); http://dx.doi.org/10.1016/j.acha.2012.05.003
we conclude that $h\mathbb{Z}^d$ is also a Bessel set of $L^2(\mu)$. As a Bessel set is invariant under translation, we see that the finite union $\mathbb{Z}^d = \bigcup_{k \in \{0, \ldots, n-1\}^d} (h\mathbb{Z}^d + k)$ is again a Bessel set of $L^2(\mu)$, which proves the claim.

Now consider

$$G(x) := \sum_{n \in \mathbb{Z}^d} |\hat{\mu}(x + n)|^2.$$  

$G$ is a periodic function (mod $\mathbb{Z}^d$). As $\mathbb{Z}^d$ is a Bessel set, applying the definition to $e^{2\pi i \langle x, \cdot \rangle}$, we see that $G(x) \leq B < \infty$. Hence $G \in L^1([0, 1)^d)$ and

$$\int_{[0, 1)^d} |\hat{\mu}(x)|^2 \, dx = \sum_{n \in \mathbb{Z}^d} \int_{[0, 1)^d} |\hat{\mu}(x + n)|^2 \, dx = \int_{[0, 1)^d} G(x) \, dx < \infty.$$  

This means that $\hat{\mu} \in L^2(\mathbb{R}^d)$, which implies $\mu$ must be absolutely continuous. This is a contradiction.

(iii) If $\mu$ is absolutely continuous, then the density function must be bounded above and below almost everywhere on the support of $\mu$ [13, Theorem 1.1]. Hence, $A$ is an F-spectrum of $L^2(\Omega)$, where $\Omega$ is the support of $\mu$. By Landau's density theorem, $D^{-} A = \mathcal{L}(\Omega) > 0$. □

Now it is easy to conclude that an F-spectral measure is of pure type.

**Proof of Theorem 1.1.** First let us assume that if $\mu$ is decomposed into non-trivial discrete and continuous parts, $\mu = \mu_d + \mu_c$. Let $A$ be an F-spectrum of $\mu$. As $L^2(\mu_d)$ and $L^2(\mu_c)$ are non-trivial subspaces of $L^2(\mu)$, it is easy to see that $A$ is also an F-spectrum of both $L^2(\mu_d)$ and $L^2(\mu_c)$. Then $\# A < \infty$ by Proposition 2.1(i); but $\# A = \infty$ since $L^2(\mu_c)$ is an infinite dimensional Hilbert space. This contradiction shows that $\mu$ is either discrete or purely continuous.

Suppose $\mu$ is continuous and has non-trivial singular part $\mu_d$ and absolutely continuous part $\mu_c$. By applying the same argument as the above, $A$ is an F-spectrum of $L^2(\mu_c)$ and $L^2(\mu_d)$. This is impossible in view of the Beurling density of $A$ in Proposition 2.1(ii) and (iii). □

The following corollary is immediate from Theorem 1.1.

**Corollary 2.2.** A spectral measure or an R-spectral measure must be of pure type.

3. Discrete measures

In this section, we will show that all discrete measures on $\mathbb{R}^d$ are R-spectral measures. By Proposition 2.1(i), we only need to consider measures with finite number of atoms. Let $C = \{c_0, \ldots, c_{n-1}\} \subset \mathbb{R}^d$ be a finite set and let

$$\mu = \sum_{c \in C} p_c \delta_c, \quad \text{with } p_i > 0, \sum_{c \in C} p_c = 1.$$  

(3.1)

For $\lambda \in \mathbb{R}^d$, we denote the vector $[e^{2\pi i \langle \lambda, c_0 \rangle}, \ldots, e^{2\pi i \langle \lambda, c_{n-1} \rangle}]^t$ by $v_\lambda$.

**Proposition 3.1.** Let $C = \{c_0, \ldots, c_{n-1}\} \subset \mathbb{R}^d$ and let $\mu$ be as in (3.1). Let $A = \{\lambda_0, \ldots, \lambda_{m-1}\} \subset \mathbb{R}^d$ be another finite set. Then

(i) $A$ is an F-spectrum of $\mu$ if and only if span$\{v_{\lambda_0}, \ldots, v_{\lambda_{m-1}}\} = \mathbb{C}^n$.

(ii) $A$ is an R-spectrum of $\mu$ if and only if $m = n$ in the above identity.

**Proof.** (i) Suppose first $A$ is an F-spectrum of $\mu$. Let $u = [u_0, \ldots, u_{n-1}]^t$ be such that $\langle u, v_{\lambda_i} \rangle = 0$ for all $i$. Consider $f$ as a function defined on $C$ with $f(c) = u_i/p_c$. By using the lower bound of the Fourier frame, we have

$$A \sum_{c \in C} |f(c)|^2 p_c \leq \sum_{\lambda \in A} \left| \sum_{c \in C} f(c) e^{2\pi i \langle \lambda, c \rangle} p_c \right|^2 = \sum_{\lambda \in A} |\langle u, v_\lambda \rangle|^2 = 0.$$  

It follows that $f(c) = 0$ for all $c \in C$, hence $u = 0$ and the necessity in (i) follows.

Conversely, the assumption implies that the vectors $v_{\lambda_0}, \ldots, v_{\lambda_{m-1}}$ form a frame on $\mathbb{C}^n$ (see [2, Corollary 1.1.3]), i.e., there exist $A, B > 0$ such that for all $u = [u_0, \ldots, u_{n-1}]^t \in \mathbb{C}^n$,

$$A \sum_{i=0}^{n-1} |u_i|^2 \leq \sum_{\lambda \in A} |\langle u, v_\lambda \rangle|^2 \leq B \sum_{i=0}^{n-1} |u_i|^2.$$  

Please cite this article in press as: X.-G. He et al., Exponential spectra in $L^2(\mu)$, Appl. Comput. Harmon. Anal. (2012), http://dx.doi.org/10.1016/j.acha.2012.05.003
For any \( f \in L^2(\mu) \), we take \( u = [f(c_0)p_{c_0}, \ldots, f(c_{n-1})p_{c_{n-1}}]^T \), we see that \( \Lambda \) is a frame with lower bound \((\min_i p_i)B\) and upper bound \((\max_i p_i)B\).

(ii) is clear from (i). \( \square \)

**Proof of Theorem 1.2.** Let \( C = [c_0, \ldots, c_{n-1}] \). We first establish the theorem for \( C \subseteq \mathbb{R}^1 \). Let \( W = \text{span}\{v_\lambda: \lambda \in \mathbb{R}^1\} \), it suffices to show that \( W = \mathbb{C}^n \). Then we can select \( \{\lambda_0, \ldots, \lambda_{n-1}\} \subseteq \mathbb{R}^1 \) so that \( \{v_{\lambda_0}, \ldots, v_{\lambda_{n-1}}\} \) a basis of \( \mathbb{C}^n \). The theorem for \( \mathbb{R}^1 \) will follow from Proposition 3.1(ii).

To see \( W = \mathbb{C}^n \), it suffices to show that if \( \langle u, v_\lambda \rangle = 0 \) for all \( \lambda \in \mathbb{R} \), then \( u = 0 \). To this end, we write \( u = [u_0, \ldots, u_{n-1}]^T \), and the given condition is

\[
\sum_{i=0}^{n-1} u_i e^{2\pi i \lambda_i} = 0.
\]

We differentiate the expression with respect to \( \lambda \) for \( k \) times with \( k = 1, \ldots, n-1 \), then

\[
\sum_{i=0}^{n-1} u_i e^{2\pi i \lambda_i} = 0.
\]

This means

\[
\begin{bmatrix}
1 & 1 & \cdots & 1 \\
c_0 & c_1 & \cdots & c_{n-1} \\
\vdots & \vdots & & \vdots \\
c_{n-1} & c_{n-1} & \cdots & c_1
\end{bmatrix}
\begin{bmatrix}
\begin{bmatrix} u_0 e^{2\pi i \lambda_0} \\
u_1 e^{2\pi i \lambda_1} \\
\vdots \\
u_{n-1} e^{2\pi i \lambda_{n-1}}
\end{bmatrix}
\end{bmatrix}
= 0.
\]

As all \( c_i \) are distinct, the Vandermonde matrix is invertible. Hence,

\[
\begin{bmatrix}
\begin{bmatrix} u_0 e^{2\pi i \lambda_0} \\
u_1 e^{2\pi i \lambda_1} \\
\vdots \\
u_{n-1} e^{2\pi i \lambda_{n-1}}
\end{bmatrix}
\end{bmatrix} = 0.
\]

and thus \( u = 0 \). This completes the proof of the theorem for \( \mathbb{R}^1 \).

On \( \mathbb{R}^d \), we note that by Proposition 3.1, \( \{c_0, \ldots, c_{n-1}\} \) admits an R-spectrum \( \{\lambda_0, \ldots, \lambda_{n-1}\} \) if and only if \( \{Qc_0, \ldots, Qc_{n-1}\} \) admits an R-spectrum \( \{Q\lambda_0, \ldots, Q\lambda_{n-1}\} \), where \( Q \) is any orthogonal transformation on \( \mathbb{R}^d \). Now given any \( \{c_0, \ldots, c_{n-1}\} \) on \( \mathbb{R}^d \), we let \( \ell_{ij} \) be the line passes through two points \( c_i, c_j \), and choose a line \( \ell \) such that \( \ell \) is not perpendicular to any \( \ell_{ij} \). Apply an orthogonal transformation \( Q \) so that the first axis coincides with the direction of \( \ell \). In this way the construction shows that the first coordinates of \( Qc_0, \ldots, Qc_{n-1} \) are all distinct.

We then apply the same argument as in \( \mathbb{R}^1 \) above, using partial differentiation with respect to the first coordinates which are all distinct, the Vandermonde matrix is invertible, hence the theorem follows. \( \square \)

**Remark 1.** If \( c_0, \ldots, c_{n-1} \) have rational coordinates, then we can choose elements \( \Lambda \) to have rational coordinates also. To see this, by multiplying an integer, we can assume that \( \{c_0, \ldots, c_{n-1}\} \) are in \( \mathbb{Z}^d \), we consider the determinant function

\[
\varphi(\lambda) = \varphi(\lambda_0, \ldots, \lambda_{n-1}) = \det
\begin{bmatrix}
e^{2\pi i (\lambda_0, c_0)} & \cdots & e^{2\pi i (\lambda_1, c_{n-1})} \\
\vdots & \ddots & \vdots \\
e^{2\pi i (\lambda_{n-1}, c_0)} & \cdots & e^{2\pi i (\lambda_{n-1}, c_{n-1})}
\end{bmatrix}
\]

with \( \lambda = (\lambda_0, \ldots, \lambda_{n-1}) \) on \( \mathbb{R}^{dn} \). Then \( \varphi(\lambda) \) is a trigonometric polynomial on \( \mathbb{R}^{dn} \), whose zero set is a closed set of Lebesgue measure zero. We can choose \( \lambda \) so that \( \varphi(\lambda) \neq 0 \) and \( \lambda \) is rational, and Proposition 3.1(ii) shows that \( \Lambda = \{\lambda_0, \ldots, \lambda_{n-1}\} \) is an R-spectrum will rational coordinates.

**Remark 2.** The R-spectrum shown in Theorem 1.2 is not explicit. It is also not easy to see whether a given set \( \Lambda \) is an R-spectrum since the invertibility of the matrix is not easy to establish in general. A probabilistic approach of finding such \( \Lambda \) in the case of trigonometric polynomials was given in [1]. The work gave a theoretical background on the theory of reconstruction of multivariate trigonometric polynomials via random sampling sets.

To carry out Theorem 1.2 further, we consider the condition that a discrete measure to be an orthogonal spectral measure. We will restrict consideration on the one-dimensional case, and by translation, we can assume, without loss of generality, that \( C \subseteq \mathbb{Z}^+ \) and \( 0 \in C \). The mask polynomial of \( \mu = \sum_{x \in C} p_x \delta_x \) is

\[
m_{C, \mu}(x) = \tilde{\mu}(x) = \sum_{x \in C} p_x e^{2\pi i x}.
\]

In case \( P \) is a set of equal probability, then we just use the notation \( m_C(x) \). We call a set \( \Lambda \) a bi-zero set of \( m_C, p \) if \( 0 \in \Lambda \) and \( m_C, p(\lambda_i - \lambda_j) = 0 \) for distinct \( \lambda_i, \lambda_j \in \Lambda \). It is clear that such \( E(\Lambda) \) is an orthogonal set in \( L^2(\mu) \).

\[\text{Please cite this article in press as: X.-G. He et al., Exponential spectra in } L^2(\mu), \text{ Appl. Comput. Harmon. Anal. (2012), http://dx.doi.org/10.1016/j.acha.2012.05.003}\]
Proposition 3.2. Let \( C \subseteq \mathbb{Z} \) be a finite set, and let \( \mu = \sum_{c \in C} p_c \delta_c \). Then \( \mu \) is a spectral measure if and only if there is a bi-zero set \( \Lambda \) of \( m_{C, \Lambda} \) and \( \#C = \#\Lambda \). In this case, all the \( p_c \)’s are equal.

Proof. Note that \( \mu \) is a spectral measure if and only if there exists a set \( \Lambda = \{\lambda_1, \ldots, \lambda_n\} \) with \( n = \#C \) such that \( \mu(\lambda_i - \lambda_j) = 0 \) for all \( i \neq j \). Since \( \mu(x) = m_{C, \Lambda}(x) \), this is equivalent to \( \Lambda \) is a bi-zero set of \( m_{C, \Lambda} \) and \( \#C = \#\Lambda \).

To see that all the \( p_c \) are equal, we put \( f = \chi_c \) into the Parseval’s identity,

\[
\sum_{\lambda \in \Lambda} |\langle f, e^{2\pi i (\lambda, x)} \rangle|^2 = \|f\|^2.
\]

We obtain \( \sum_{\lambda \in \Lambda} p_c^2 = p_c \). Hence, \( p_c = 1/\#\Lambda = 1/\#C \).

In the following we use Proposition 3.2 to obtain explicit expressions of \( C \) with \( \#C \leq 4 \) that are discrete spectral measures. It is trivial to check that when \( \#C = 1, 2 \), the associated \( \mu \) is always a spectral measure.

Example 3.3. Let \( C = \{c_0 = 0, c_1, c_2\} \subseteq \mathbb{Z}^+ \) with gcd\( (C) = 1 \). Then \( \mu = \sum_{c \in C} \delta_c \) is a spectral measure if and only if \( c_2 = 2c_1 \mod 3 \) (i.e., \( C \) is a complete residue \( \mod 3 \)).

Proof. For the sufficiency, we write \( c_1 = 3k + i, i = 1, 2 \) and \( k \in \mathbb{N} \). Then \( c_2 = 3l + 2i \) and

\[
\{0, c_1, c_2\} = \{0, 1, 2\} \mod 3.
\]

It is direct to check that \( \Lambda = \{0, 1, 2\} \) is a bi-zero set of \( m_C(x) \) with \( \#A = \#C \) and hence \( \mu \) is a spectral measure.

For the necessity, we let \( \Lambda = \{0, \lambda_1, \lambda_2\} \) be such that \( m_C(b_1) = m_C(b_2) = 0 \). Note that \( m_C(x) = 1 + e^{2\pi i c_1 x} + e^{2\pi i c_2 x} \). Then \( m_C(x) \) has roots in \( (0, 1) \) if and only if \( e^{2\pi i c_1 x} = e^{2\pi i/3}, e^{2\pi i c_2 x} = e^{2\pi i/3} \) (or the other way round). Hence there exists \( k, l \in \mathbb{Z}^+ \) such that

\[
2\pi c_1 x = 2k\pi + \frac{2\pi}{3}, \quad 2\pi c_2 x = 2l\pi + \frac{4\pi}{3}.
\]

It follows that \( x = \frac{3k + 1}{c_1} = \frac{3l + 2}{c_2} \). Since gcd\( (c_1, c_2) = 1 \), we have \( 3k + 1 = c_1 m \) and \( 3l + 2 = c_2 m \). Hence \( 3 \mid m \), and \( 3 \mid (c_2 - 2c_1) \).

This implies the sufficiency.

Example 3.4. Let \( C = \{c_0 = 0, c_1, c_2, c_3\} \subseteq \mathbb{Z}^+ \) with gcd\( (C) = 1 \). Then \( \mu \) is a spectral measure if and only if after rearrangement, \( c_1 \) is even, \( c_2, c_3 \) are odd, and \( c_1 = 2^\alpha (2k + 1), c_2 - c_3 = 2^\alpha (2\ell + 1) \) for some \( \alpha > 0 \).

Proof. We first prove the necessity. The mask polynomial of \( \mu \) is \( m_C(x) = 1 + e^{2\pi i c_1 x} + e^{2\pi i c_2 x} + e^{2\pi i c_3 x} \). That \( m_C(x) = 0 \) implies

\[
\left| 1 + e^{2\pi i c_1 x} \right| = \left| 1 + e^{2\pi i (c_3 - c_2) x} \right|,
\]

which yields (i) \( e^{2\pi i c_1 x} = e^{2\pi i (c_3 - c_2) x} \) or (ii) \( e^{2\pi i c_1 x} = e^{-2\pi i (c_3 - c_2) x} \). Putting (i) into \( m_C(x) = 0 \), we have \( (1 + e^{2\pi i c_1 x})(1 + e^{2\pi i c_2 x}) = 0 \). Hence we have two sets of equations:

\[
2c_1 x = 2k + 1; \quad 2(c_3 - c_2) x = 2l + 1.
\]

or

\[
2c_2 x = 2k + 1; \quad 2(c_3 - c_1) x = 2l + 1.
\]

From (3.3), we have \( x = \frac{2k + 1}{c_1}, \frac{2l + 1}{c_3 - c_2} \). Let \( a = \gcd(c_1, c_2 - c_3) \). It is easy to show that there exists \( m \) such that

\[
2k + 1 = \frac{c_1 m}{a}, \quad 2l + 1 = \frac{(c_3 - c_2) m}{a}.
\]

Hence \( m, c_1/a, (c_3 - c_2)/a \) must be odd. Also note that \( \gcd(c_1, c_2, c_3) = 1 \), it follows from a direct check of the above that two of the \( c_1, c_2, c_3 \) must be odd, and one must be even (all three cases can happen).

The same argument applies to (3.4) and to (ii). The last statement also follows in the proof.

To prove the sufficiency, we first observe from the above that for \( c_1 \) even, \( c_2, c_3 \) odd, there are solutions \( x_1, x_2 \in (0, 1) \) from (i) (see (3.3)-(3.5)):

\[
x_1 = \frac{2i + 1}{2a}, \quad 0 \leq i < a; \quad x_2 = \frac{2j + 1}{2b}, \quad 0 \leq j < b.
\]
where gcd(c₁, c₂ − c₃) as above, and b = gcd(c₂, c₁ − c₁). Since b is odd, we can take 2j + 1 = b, so that x₂ = 1/2 is a solution of mₙ(x) = 0. Let
\[ \lambda_1 = \frac{1}{2}, \quad \lambda_2 = \frac{1}{2a}, \quad \lambda_3 = \frac{2^\alpha \text{gcd}(r, s) + 1}{2a}, \]
where c₁ = 2^α r, c₂ = 2^α s and r, s are odd integers as in the assumption. We claim that \( \Lambda = \{0, \lambda_1, \lambda_2, \lambda_3\} \) is a bi-zero set of \( mₙ(x) \). Indeed, since \( a = 2^\alpha \text{gcd}(r, s) \), \( \lambda_1 - \lambda_2 = (a - 1)/2a \) is of the form \( x₁ \) for \( i = 2^\alpha - 1 \text{gcd}(r, s) - 1 \), \( \lambda_3 - \lambda_1 = \lambda_2 \) and \( \lambda_3 - \lambda_2 = \lambda_1 \), the claim follows. \( \square \)

For \#C large, it is difficult to evaluate the zero set of the mask polynomial. However there is a number-theoretical approach to study such zeros related to the spectrum and integer tiling, this is to be discussed in the next section and in Appendix A.

4. A connection with integer tiles

In this section we will give a brief discussion of the relationship between discrete spectral measures and integer tiles, and provide the tools we need in the next section. Let \( \mathcal{A} \subset \mathbb{Z}^+ \) and assume that \( 0 \in \mathcal{A} \), we say that \( \mathcal{A} \) is an integer tile if there exists \( T \) such that \( \mathcal{A} \oplus T = \mathbb{Z} \), i.e., \( \mathcal{A} + \{0, 1\} \) is a spectral measure. Equivalently, \( \mathcal{A} \) is a tile if there exists \( \mathcal{B} \) and \( n \) such that
\[ \mathcal{A} \oplus \mathcal{B} \equiv \mathbb{Z}_n \ (\text{mod } n). \tag{4.1} \]

Recall that the Fuglede conjecture asserts that for \( \Omega \subset \mathbb{R}^d \) with positive measure, \( \Omega \) is a translational tile if and only if the restriction of the Lebesgue measure \( \mathcal{L}|_{\Omega} \) is a spectral measure. Although the conjecture is proved to be false in either direction [26,12], it remains unanswered for dimension 1 and 2, and for some special classes of tiles in any dimension.

Let \( \mathcal{A} \) be a finite subset in \( \mathbb{Z} \), then the Fuglede conjecture reduces to \( \mathcal{A} \) is an integer tile if and only if \( \mathcal{A} + \{0, 1\} \) is a spectral set, i.e., \( \mathcal{L}_{\mathcal{A} + \{0, 1\}} \) is a spectral measure. It is also known that the latter part is also equivalent \( \delta_{\mathcal{A}} = \sum_{a \in \mathcal{A}} \delta_a \) is a discrete spectral measure [22]. This also follows from Theorem 5.3 in Section 5. In Example 3.3, the spectral condition for \#C = 3 is equivalent to \( C \) is a complete residue (mod 3), which trivially satisfies (4.1). Hence the conjecture is true for \#C = 3. In Example 3.4, the spectral condition is equivalent to
\[ C = \{0, 2^\alpha (2k + 1), 2r + 1, 2r + 1 + 2^\alpha (2\ell + 1)\} \]
for some non-negative integers \( k, r, \ell \). If we let \( \mathcal{B} = \{0, 2\} \oplus \cdots \oplus \{0, 2^{\alpha - 1}\} \), then it is direct to check that \( C \oplus \mathcal{B} \equiv \mathbb{Z}_{2^{\alpha + 1}} \) (mod \( 2^{\alpha + 1} \)). Hence by (4.1), the conjecture is true for \#C = 4. Actually, by using some deeper number-theoretic argument (see Appendix A), it can be shown that if \#C = \( p^a q^d \) where \( p, q \) are distinct primes, then \( C \) is an integer tile implies it is a spectral set [3,14].

The following is a useful sufficient condition of a discrete spectral measure. The condition trivially imply the underlying set is an integer tile.

**Theorem 4.1.** Let \( \mathcal{A} \subset \mathbb{Z}^+ \) be a finite set with \( 0 \in \mathcal{A} \). Suppose there exists \( \mathcal{B} \subset \mathbb{Z}^+ \) such that
\[ \mathcal{A} \oplus \mathcal{B} = \mathbb{N}_n \]
where \( \mathbb{N}_n = \{0, \ldots, n - 1\} \). Then the discrete measure \( \delta_{\mathcal{A}} = \sum_{a \in \mathcal{A}} \delta_a \) (with equal weight) is a spectral measure with a spectrum contained in \( \frac{1}{n} \mathbb{Z} \).

The theorem was due to [24] (and also in [6]), and the proof involves an inductive construction of the spectrum. The spectrum is implicit and the proof is long. We will provide an alternative proof using the properties of the root of unity as the zeros of the mask polynomial. The framework is from [3] and the spectrum is explicitly given in [14]. Because of the number-theoretical notations and techniques, we will leave the details in Appendix A.

Finally, we state a related theorem of the self-similar measures which follows from the known results, and will be needed in the next section.

**Theorem 4.2.** Let \( \mathcal{A} \subset \mathbb{Z}^+ \) be a finite set with \( 0 \in \mathcal{A} \). Suppose there exists \( \mathcal{B} \subset \mathbb{Z}^+ \) such that \( \mathcal{A} \oplus \mathcal{B} = \mathbb{N}_n \). Let \( \mu \) be the self-similar measure satisfying
\[ \mu(\cdot) = \frac{1}{\#\mathcal{A}} \sum_{a \in \mathcal{A}} \mu(\cdot - a). \]
Then \( \mu \) is a spectral measure. Moreover, if \( \text{gcd}(\mathcal{A}) = 1 \), then the spectrum \( \Lambda \) of \( \mu \) can be chosen to be in \( \mathbb{Z} \).
\textbf{Proof.} Denote the spectrum of \( \delta_A \) in Theorem 4.1 by \( S \) with \( S \subset \frac{1}{2} \mathbb{Z} \), then \( (A, S) \) form a compatible pair as in [15], i.e.,
\[
\frac{1}{\# A} \left[ e^{2\pi i a s} \right]_{a, s \in S}
\]
is a unitary matrix. The theorem follows from [15, Theorem 1.2]. For the last part, since we can change the residue representatives of \( \Gamma' \) with \( S = \frac{1}{2} \Gamma' \) and \( \Gamma' \subset (-n - 2, \ldots, n - 2) \). With \( \gcd(A) = 1 \), Theorem 1.2 in [15] states that
\[
\Lambda = \Gamma' \oplus n \Gamma' \oplus n^2 \Gamma' \oplus \cdots
\]
is a spectrum. This spectrum clearly lies in \( \mathbb{Z} \). \qed

\textbf{Remark.} For the 1/4-Cantor measure, \( \mu(\cdot) = \frac{1}{2} \mu(4) + \frac{1}{2} \mu(4 \cdot -2) \). It is easy to compute the Fourier transform is \( \hat{\mu}(\xi) = e^{2\pi i 4 \xi} \prod_{j=1}^{\infty} \cos(2\pi \xi/4^j) \) and the zero set of \( \hat{\mu} \) is \( \mathbb{Z}_{\mu} = \{ 4^j a : a \text{ is odd and } j \geq 0 \} \). Note that \( A = \{0, 2\} \) and the condition of the theorem is satisfied, the spectrum of \( \mu \) can be taken as [11]
\[
\Lambda = \{0, 1\} \oplus \{0, 1\} \oplus 4 \{0, 1\} \oplus \cdots \subset \mathbb{Z}_{\mu}.
\]
However the condition \( A \oplus B = \mathbb{N}_0 \) in Theorem 4.2 is quite restrictive. For the 1/6-Cantor measure, \( \mu(\cdot) = \frac{1}{2} \mu(6) + \frac{1}{2} \mu(6 \cdot -2) \), according to [11], it is again a spectral measure and the spectrum is
\[
\Lambda = \frac{3}{2} \{0, 1\} \oplus \{0, 1\} \oplus 6 \{0, 1\} \oplus \cdots \}
\]
But for \( A = \{0, 2\} \) in this case, we cannot find \( B \) so that \( A \oplus B = \mathbb{N}_0 \). Also, \( \mu \) does not admit spectrum \( \Lambda' \subset \mathbb{Z} \). The proof is as follows: If so, observe that
\[
\Lambda' \subset \mathbb{Z}_{\mu} = \{6^j a/4 : a \text{ is odd and } j \geq 1\}.
\]
As \( \lambda \) is an integer, we see that for \( \lambda \in \Lambda', \lambda = 6^j a/4 \), and \( n \geq 2 \) necessarily. Let \( x = 3/2 \), then \( x \in \mathbb{Z}_{\mu} \setminus \Lambda' \) and \( x - \lambda = 6(1 - 6^{j-1} a)/4 \in \mathbb{Z}_{\mu} \). This means \( \sum_{\lambda \in \Lambda} |\hat{\mu}(x - \lambda)|^2 = 0 \), which shows that \( \Lambda' \) cannot be a spectrum by Proposition 5.2.

5. Convolutions

Let \( \nu \) be a probability measure with compact support \( \Omega \subset [0, 1] \) and let \( \eta \) be a discrete probability measure with support on \( C \subset \mathbb{Z}^+ \) and probability weight \( P \), i.e. \( \eta = \delta_{C, P} = \sum_{c \in C} P_c \delta_c \). Then \( \mu = \eta \ast \nu \) has support on \( C \cup \Omega \). Given a non-negative integer \( q \), we let \( \eta_q = \delta_{C, p} \).

\textbf{Theorem 5.1.} Let \( \nu \) be an R-spectral measure with a spectrum \( \Gamma' \) and assume that there exists an integer \( q \geq 1 \) such that \( q \Gamma' \subset \mathbb{Z} \). Then \( \mu := \eta_q \ast \nu \) is an R-spectral measure.

\textbf{Proof.} We write \( A = qC = \{0 = a_0, a_1, \ldots, a_{k-1}\} \). By Theorem 1.2, there exists an R-spectrum of \( A \) which we denote it as \( S = \{0 = s_0, s_1, \ldots, s_{k-1}\} \). By Proposition 3.1(ii), we see that
de\[\text{det}\left[ e^{2\pi i a s} \right]_{a, s \in S} = 0.\]
We will show that \( S \oplus \Gamma' \) is an R-spectrum of \( \mu \).
Since \( \Omega = \text{supp}(\nu) \subset [0, 1] \), for any \( f \in L^2(\mu) \), \( f \) is uniquely determined by the vector-valued function \( [f(x + a_0), \ldots, f(x + a_{k-1})]^\top \) on \( \Omega \). Let \( M = [e^{2\pi i a s}]_{a, s \in S} \), it is invertible. We define
\[
\left[ g_0(x), \ldots, g_{k-1}(x) \right] = M^{-1} \left[ f(x + a_0), \ldots, f(x + a_{k-1}) \right] \quad \in \Omega.
\]
Clearly \( g_j \in L^2(\nu) \) for \( 0 \leq j \leq k - 1 \). It is easy to see \( s_j + \Gamma' \) is also an R-spectrum of \( \nu \), so that \( g_j \) can be uniquely expressed as
\[
g_j(x) = \sum_{y \in \Gamma'} c_{s_j + y} e^{2\pi i (s_j + y) x}.\]
Hence, we have
\[
M \left[ g_0(x), \ldots, g_{k-1}(x) \right]^\top = \left[ \sum_{j=0}^{k-1} e^{2\pi i a_0 s_j} g_j(x), \ldots, \sum_{j=0}^{k-1} e^{2\pi i a_{k-1} s_j} g_j(x) \right]^\top,
\]
Proposition 5.2. Let $\mu$ be a probability measure on $\mathbb{R}^d$ with compact support. Then $\Lambda$ is an orthogonal spectrum of $\mu$ if and only if

$$Q(x) = \sum_{\lambda \in \Lambda} |\hat{\mu}(x + \lambda)|^2 = 1, \quad x \in \mathbb{R}. $$

In particular, if $\mu = \sum_{c \in C} p_c \delta_c$ is a discrete spectral measure with spectrum $\Lambda$, then $p_c = 1/|C|$ by Proposition 3.2 and

$$\sum_{\lambda \in \Lambda} |m_{c, p}(x + \lambda)|^2 = 1. $$

To determine whether $\mu$ in Theorem 5.1 is a spectral measure, we have the following simple characterization.

Theorem 5.3. Let $\nu$ be an R-spectral measure and suppose $q\mathcal{Z}_\nu \subset \mathbb{Z}$. Then $\mu = \eta_\nu * \nu$ is a spectral measure if and only if both $\eta$ and $\nu$ are spectral measures.

Proof. It is clear that $\eta$ is a spectral measure if and only if $q\mathcal{Z}_\eta$ is also a spectral measure. We first prove the sufficiency. Let $\mathcal{A} = q\mathcal{C}$, and let $S = \{0, s_1, \ldots, s_{k-1}\}$ be a bi-zero set of $\mathcal{A}$ (note that $P$ is a set of equal weights by Proposition 3.2). Let $\Gamma$ be a spectrum of $\nu$, then $q\mathcal{Z}_\nu \subset \mathbb{Z}$ by the hypothesis that $q\mathcal{Z}_\nu \subset \mathbb{Z}$. The Fourier transform of $\mu$ satisfies

$$\hat{\mu}(\xi) = m_{A, P}(\xi) \widehat{\nu}(\xi).$$

By the spectral property of $S$ and $\Gamma$,

$$\sum_{0 \leq j \leq k-1} |\hat{\mu}(x + s_j + \gamma)|^2 = \sum_{0 \leq j \leq k-1} |m_{A, p}(x + s_j + \gamma)|^2 |\widehat{\nu}(x + s_j + \gamma)|^2 = \sum_{0 \leq j \leq k-1} |m_{A, p}(x + s_j)|^2 = 1.$$ 

Hence $S \oplus \Gamma$ is an orthogonal spectrum of $\mu$ by Proposition 5.2.

Conversely, suppose that $A$ is a spectrum of $\mu$ and without loss of generality assume $0 \in A$. Denote $x = |x| + [x]$ where $[x]$ is the maximum integer which is less than or equal to $x$. We claim that $S = \{q^{-1}[\lambda]\lambda: \lambda \in \Lambda\}$ is a bi-zero set of $m_{A, p}$.

Indeed, by writing $\lambda = q^{-1}[\lambda] + q^{-1}[\lambda]$, we have

$$0 = \hat{\mu}(\lambda) = m_{A, p}(q^{-1}[\lambda] + q^{-1}[\lambda]) \widehat{\nu}(\lambda) = m_{A, p}(q^{-1}[\lambda]) \widehat{\nu}(\lambda)$$

for each $\lambda \in A$. Note that $\widehat{\nu}(\lambda) = 0$ implies $q\lambda \in \mathbb{Z}$ (by the assumption $q\mathcal{Z}_\nu \subset \mathbb{Z}$), so that $[q\lambda] = 0$. (5.2) implies that either $q^{-1}[q\lambda] = 0$ or it is a root of $m_{A, p}$. For any given distinct $q^{-1}[\lambda_1]$, $q^{-1}[\lambda_2] \in S$ and $[q\lambda_1] > [q\lambda_2]$, we have $q^{-1}[q(\lambda_1 - \lambda_2)] = q^{-1}(q(\lambda_1) - q(\lambda_2))$ is a root of $m_{A, p}$. This proves the claim.

Let us write $A = \bigcup_{j=0}^{k-1} (s_j + A_j)$, $s_j \in S$, where $A_j = \{q^{-1}[\lambda]: q^{-1}[q\lambda] = s_j\}$. Since $A$ is a spectrum of $\mu$, we must have for all $\lambda_1, \lambda_2 \in A_j$,

$$0 = \hat{\mu}(\lambda_1 - \lambda_2) = m_{A, p}(\lambda_1 - \lambda_2) \nu(\lambda_1 - \lambda_2).$$

Note that the last equality follows from $\gamma a_i = (q\gamma)c_j$ is an integer by the assumption $q\Gamma \subset \mathbb{Z}$. By a change of variable with $y = x + a_i$ for each $i$, we have

$$f(y) = \sum_{0 \leq j \leq k-1} |m_{A, p}(x + s_j + \gamma)|^2 |\widehat{\nu}(x + s_j + \gamma)|^2 = \sum_{0 \leq j \leq k-1} |m_{A, p}(x + s_j)|^2 = 1.$$ 

It is easy to see that the above representation is unique, this means $E(S + \Gamma)$ is both a basis and a frame of $L^2(\mu)$. Hence $E(S + \Gamma)$ is a Riesz basis. □
But $a(q^{-1}[q,1]) \in \mathbb{Z}$ for all $a \in A = qC$, this shows $m_{A,p}(\lambda_1 - \lambda_2) \neq 0$ and hence $\nu(\lambda_1 - \lambda_2) = 0$. Therefore $E(A_j)$, $0 \leq j \leq k - 1$, are the orthogonal set of $\nu$. By the Bessel inequality, $\sum_{\lambda \in A_j} |\hat{\nu}(x + s_j + \lambda)|^2 \leq 1$. Note further that $S$ is a bi-zero set of $m_{A,p}$. By Proposition 5.2, we have

$$1 \equiv \sum_{\lambda \in A} |\hat{\mu}(x + \lambda)|^2 = \sum_{j=0}^{k-1} \sum_{\lambda \in A_j} |\hat{\mu}(x + s_j + \lambda)|^2$$

$$= \sum_{j=0}^{k-1} \sum_{\lambda \in A_j} |m_{A,p}(x + s_j + \lambda)\hat{\nu}(x + s_j + \lambda)|^2$$

$$= \sum_{j=0}^{k-1} \sum_{\lambda \in A_j} |m_{A,p}(x + s_j)\hat{\nu}(x + s_j + \lambda)|^2 \quad \text{(since } a\lambda \in \mathbb{Z})$$

$$\leq \sum_{j=0}^{k-1} |m_{A,p}(x + s_j)|^2 \leq 1.$$  

Hence $S$ is the orthogonal spectrum of $\eta$ by Proposition 5.2 again, so that $\eta$ is a spectral measure. From the third line of the above, we also have

$$1 \equiv \sum_{j=0}^{k-1} |m_{A,p}(x + s_j)|^2 \sum_{\lambda \in A_j} |\hat{\nu}(x + s_j + \lambda)|^2.$$  

With $\sum_{j=0}^{k-1} |m_{A,p}(x + s_j)|^2 \equiv 1$, we must have $\sum_{\lambda \in A_j} |\hat{\nu}(x + s_j + \lambda)|^2 \equiv 1$. Hence, $\nu$ is a spectral measure and any one of the $A_j$ is a spectrum of $\nu$. \qed

It has been an open question whether the 1/3-Cantor measure has an F-spectrum (or even an R-spectrum). To a less extend, we do not know a non-trivial singularly continuous R-spectral measure. In the following, we can make use of Theorems 5.1 and 5.3 to construct such measures.

**Example 5.4.** There exists a singularly continuous R-spectral measure which is not a spectral measure.

**Proof.** Consider the self-similar measure $\nu_{A,n}$ in Theorem 4.2 with $A$ satisfying $A \oplus B = \mathbb{N}_n$ and $\gcd(A) = 1$. It is a spectral measure and has a spectrum $T' \subset \mathbb{Z}$. Moreover we claim that $Z_v \subset \mathbb{Z}$. Indeed, observe that

$$\hat{\nu}(\xi) = \sum_{j=1}^{\infty} \prod_{\lambda \in A} \left( \frac{\xi}{n^j} \right)$$

where $m_A$ stands for the mask polynomial of $A$ under equal weight. As $A \oplus B = \mathbb{N}_n$, we have

$$m_A(\xi)m_B(\xi) = 1 + e^{2\pi i\xi} + \cdots + e^{2\pi i(n-1)\xi}.$$  

The zero set of $m_A$ on $[0, 1)$ is a finite subset $Z \subset \{1/n, \ldots, n-1/n\}$. Let $Z' = Z + \mathbb{Z}$. This shows that $Z_v = \bigcup_{j=1}^{\infty} j! \cdot Z'$. This proves the claim and the condition in Theorem 5.3 holds (taking $q = 1$).

Now we let $\eta = \delta_C \ast \nu_{A,n}$ be a discrete measure with any finite set $C$ of non-negative integers and non-uniform weight $P$. $\mu = \eta \ast \nu_{A,n}$ is an R-spectral measure but not a spectral measure by Theorem 5.1 and Theorem 5.3. These measures is clearly singular if $\#A < n$. \qed

Finally, if $E$ is a Borel set with positive Lebesgue measure, we use $L^2(E)$ to denote the square integrable functions on $E$. We remark that $L^2(E)$ always have an F-spectrum, and the existence of orthogonal spectrum is related to the transversal tile as in Fuglede’s conjecture. For R-spectrum, it is not known whether every Borel set $E$ with positive Lebesgue measure, $L^2(E)$ has an R-spectrum. In regard to this we have the following simple result.

**Corollary 5.5.** If $E$ be a finite union of closed intervals with rational endpoints. Then $L^2(E)$ admits an R-spectrum.

**Proof.** By the hypothesis and by suitably rescaling and translation, there exist two integers $r$ and $s$ such that

$$rE + s = [0, 1] + A := F,$$
where $0 \in \mathcal{A}$ and $\mathcal{A} \in \mathbb{Z}^+$ is a finite set. By Theorem 1.3 with $\nu$ being the Lebesgue measure on $[0,1]$, we see that $F$ has an R-spectrum, which implies $L^2(E)$ also has an R-spectrum. \hfill $\square$

We remark that similar results were obtained in [21] who considered the problem from the sampling point of view and used techniques in complex analysis. We do not know whether the condition of rational endpoints can be removed. In [18], the case when the end-points lying in certain groups was considered, and the above also follows as a corollary.

Appendix A. Proof of Theorem 4.1

In this section, we will prove Theorem 4.1 using a number-theoretic method. The setup is in [3]. For the trigonometric polynomial $m_{\mathcal{A}}(x) = \sum_{a \in \mathcal{A}} e^{2 \pi i a x}$, it is convenient to replace by the polynomial $P_{\mathcal{A}}(x) = \sum_{a \in \mathcal{A}} x^a$. Recall that a cyclotomic polynomial $\Phi_n(x)$ is the minimal polynomial of the $n$th root of unity. It follows that $\Phi_n(x)|P_{\mathcal{A}}(x)$ is equivalent to $m_{\mathcal{A}}(s^{-1}) = 0$.

For a finite set $\mathcal{A} \subset \mathbb{Z}^+$, we write $p$ as primes and define

$$S_{\mathcal{A}} = \left\{ p^\alpha > 1 : \Phi_{p^\alpha}(x)|P_{\mathcal{A}}(x) \right\} \quad \text{and} \quad \tilde{S}_{\mathcal{A}} = \left\{ s > 1 : \Phi_s(x)|P_{\mathcal{A}}(x) \right\}$$

and the following two conditions

(T1) $\# \mathcal{A} = \prod_{a \in S_{\mathcal{A}}} \Phi_s(1)$,
(T2) For any distinct prime powers $s_1, \ldots, s_n \in S_{\mathcal{A}}$, then $s_1, \ldots, s_n \in \tilde{S}_{\mathcal{A}}$.

Intuitively, (T1) means if $\# \mathcal{A} = \prod_{j=1}^k p_j^{a_j}$, then there is exactly $\alpha_j$ prime powers of $p_j$ in $S_{\mathcal{A}}$ (since $\Phi_{p^\alpha}(1) = p$). Also, (T2) is a generalization from the basic identity $1 + x + \ldots + x^{\delta-1} = \prod_{m=1}^{\delta} \Phi_m(x)$ to $P_{\mathcal{A}}(x)$. It is known that if a set $\mathcal{A}$ satisfies these conditions, then it is an integer tile, i.e., it tiles $\mathbb{Z}$. Conversely, if a set $\mathcal{A}$ tiles $\mathbb{Z}$, then it satisfies (T1); for (T2) it holds when $\# \mathcal{A} = p^aq^b$ for $p, q$ distinct prime numbers, and is still an open question without the additional condition. Theorem 5.8 we are going to prove is a special case of this. In another direction Laba [14] showed that (T1) and (T2) imply the spectral property:

**Proposition 5.6.** Suppose that a finite set of non-negative integers $\mathcal{A}$ satisfies (T1) and (T2). Then $\delta_{\mathcal{A}}$ is a spectral measure and has a spectrum

$$\mathcal{S} = \left\{ \sum_{s \in S_{\mathcal{A}}} k_s s^{-1} : k_s \in \{0, 1, \ldots, p - 1\} \right\}$$

The following are basic manipulation rules for the cyclotomic polynomials.

**Lemma 5.7.** Let $p$ be a prime, then

(i) $\Phi_s(px) = \Phi_{sp}(x)$ if $p|s$, and
(ii) $\Phi_s(px) = \Phi_s(x)\Phi_{sp}(x)$ if $p$ is not a factor of $s$.

It follows that if $p$ is a prime and $\Phi_{p^\alpha}(x)$ divides $P_{\mathcal{A}}(x^m)$ for some $m > 0$, then by Lemma 5.7, we have $\Phi_{p^{\alpha+\gamma}}(x)$ divides $P_{\mathcal{A}}(x^{mp})$ if $p|m$ (by (i)), and $\Phi_{p^\alpha}(x)$ divides $P_{\mathcal{A}}(x^{mp})$ if $p \nmid m$ (by (ii)). If we let $\gamma = \max\{j : p^j|m\}$ (by convention $\gamma = 0$ if $p \nmid m$) and repeat the above argument, we have $\Phi_{p^{\alpha+\gamma}}(x)|P_{\mathcal{A}}(x)$. That is

$$S_{m,\mathcal{A}} = \left\{ p^{\alpha+\gamma} : p^\alpha \in S_{\mathcal{A}}, \gamma = \max\{j : p^j|m\} \right\}.$$  

We reformulate Theorem 4.1 as the following

**Theorem 5.8.** Let $\mathcal{A} \oplus \mathcal{B} = \mathbb{N}_n$, then $\mathcal{A}$ and $\mathcal{B}$ satisfies (T1) and (T2). Hence $\delta_{\mathcal{A}}$ is a spectral measure with a spectrum in $\frac{1}{n}\mathbb{Z}$.

**Proof.** It is easy to check that both $\mathcal{A}$ and $\mathcal{B}$ satisfy condition (T1) [3]. It remains to prove condition (T2) holds. Without loss of generality we assume that $1 \in \mathcal{A}$. We use induction on the number of primes of $n$. If $n$ consists only of one prime. Then $\mathcal{A}$ equals $\{0, 1, \ldots, n - 1\}$ and (T2) holds trivially.

Let $\mathcal{A} \oplus \mathcal{B} = \mathbb{N}_n$, then by [20, Lemma 1], there exists $m \geq 2$ with $m|n$ and $\mathcal{A}' \oplus \mathcal{B}' = \mathbb{N}_m$ such that

$$\mathcal{A} = m\mathcal{A}' + \mathbb{N}_m \quad \text{and} \quad \mathcal{B} = m\mathcal{B}'.$$  

Induction hypothesis implies that (T2) holds for $\mathcal{A}'$ and $\mathcal{B}'$.

To show that $B$ has (T2), we observe that $P_B(x) = P_B(x^n)$. By (A.2)
$$S_B = \{ q^{\beta_1 y_1} : q^{\beta_1} \in S_{B'}, \gamma = \max \{ j : q^j | m \} \}.$$ 
Taking distinct prime powers in $S_B$, say $q_1^{\beta_1 + y_1}, \ldots, q_\ell^{\beta_\ell + y_\ell}$. By (T2) of $B'$, $\Phi(q_1^{\beta_1}, \ldots, q_\ell^{\beta_\ell})$ divides $P_{B'}(x)$. Hence, $\Phi(q_1^{\beta_1}, \ldots, q_\ell^{\beta_\ell})$ divides $P_B(x)$ and so is $\Phi(q_1^{\beta_1 + y_1}, \ldots, q_\ell^{\beta_\ell + y_\ell})$ by iteratively applying Lemma 5.6. This implies $B$ has (T2).

Next we consider $A$, by (A.3),
$$P_A(x) = P_A(x^n) (1 + x + \cdots + x^{n-1}) = \prod_{d|m, d > 1} \Phi_d(x).$$
We then have
$$S_A = \{ p^{\alpha + y} : p^{\alpha} \in S_A', \gamma = \max \{ j : q^j | m \} \} \cup \{ r^j : r \text{ prime}, r|m \}.$$ 
We can apply the same argument as the above to check that the product of the prime powers in $S_A$ divides $P_A(x)$, and hence $A$ has (T2).

For the last statement, we just need to note that $S_A \subset \{ d : d|n \}$ by $A \oplus B = \mathbb{N}_n$. Hence, $S$ constructed in Proposition 5.6 lies in $\frac{1}{n} \mathbb{Z}$. \(\square\)
