Spherical Image Inpainting with Frame Transformation and Data-Driven Prior Deep Networks

Jianfei Li, Chaoyan Huang, Raymond Chan, Han Feng, Michael K. Ng, and Tieyong Zeng

Abstract. Spherical image processing has been widely applied in many important fields, such as omnidirectional vision for autonomous cars, global climate modeling, and medical imaging. It is nontrivial to extend an algorithm developed for flat images to the spherical ones. In this work, we focus on the challenging task of spherical image inpainting with a deep learning-based regularizer. Instead of a naive application of existing models for planar images, we employ a fast directional spherical Haar framelet transform and develop a novel optimization framework based on a sparsity assumption of the framelet transform. Furthermore, by employing progressive encoder-decoder architecture, a new and better-performed deep CNN denoiser is carefully designed and works as an implicit regularizer. Finally, we use a plug-and-play method to handle the proposed optimization model, which can be implemented efficiently by training the CNN denoiser prior. Numerical experiments are conducted and show that the proposed algorithms can greatly recover damaged spherical images and achieve the best performance over purely using a deep learning denoiser and a plug-and-play model.

Key words. spherical image inpainting, deep CNN, plug-and-play

1. Introduction. In practical problems, a large amount of data comes in the form of spherical images, such as from cosmology [20], astrophysics [22], geophysics [1, 23], neuroscience [21], and the omnidirectional AR/VR field [2, 27], where images are naturally defined on the 2D spherical surface. Due to the storage bottleneck and observation being costly and infeasible, these spherical images (signals) usually contain very limited pixels (observed data), especially if the observation scales involved are large. Therefore, repairing missing or damaged parts is a fundamental yet challenging task in spherical image processing. Apparently, spherical images take an inherent domain different from planar images in two dimensions in terms of symmetries, coordinate systems, and translates, which demand special processing methods. In this paper, we are concerned with spherical image restoration, which can further serve as a preliminary for subsequent tasks, like object recognition and segmentation. Mathematically, it aims to estimate $x$ from observation $y$ for the following model:

\[ y = T(x) + \varepsilon, \]

(1.1)

where $T$ is a degradation operator, and $\varepsilon$ is assumed to be the additive noise. Different degradation operations correspond to different image restoration (IR) tasks [13, 14]. Typically, the IR task would be image denoising when $T$ is an identity operation, image deblurring when $T$ is a 2D convolution operation, image super-resolution when $T$ is a composite operation of convolution and downsampling, color image demosaicing when $T$ is a color filter array (CFA) masking operation, and image inpainting when $T$ is the orthogonal projection onto the linear space of matrices. In this paper, we propose a general model for spherical image inpainting with a new denoiser.

Regarding the degradation equation (1.1), the IR task model can be solved through the following optimization:

\[ \hat{x} = \arg \min_x \| y - T(x) \| + \lambda \Phi(x), \]

(1.2)

where the first term is the data fitting with $\| \cdot \|$ usually chosen to be the Frobenius norm, the second term $\Phi(\cdot)$ is an operator playing the role of regularity, and $\lambda$ is a positive trade-off parameter. With the aid of the half quadratic splitting (HQS) algorithm, by introducing an auxiliary variable, the optimization problem (1.2) can be addressed by iteratively solving the following subproblems

\[ x_k = \arg \min_x \| y - T(x) \|^2 + \alpha \| x - z_{k-1} \|^2, \]

(1.3)

\[ z_k = \arg \min_z \alpha \| z - x_k \|^2 + \lambda \Phi(z). \]

(1.4)
Here $\alpha$ will be set accordingly to specific problems. Equation (1.3) is usually interpreted as the data fitting subproblem and (1.4) as the regularization subproblem. Many research efforts have been devoted to this hot topic and achieved extensive improvements [3, 5, 11, 24, 25].

As one can see, the fidelity term and the regularization term are decoupled into two individual subproblems. Specifically, the fidelity term is associated with a quadratic regularized least-squares problem (i.e., (1.3)) which has various fast solutions for different degradation matrices. The regularization term is involved in (1.4), which can be rewritten as

$$z_{k+1} = \arg \min_z \frac{1}{2(\sqrt{\lambda/\alpha})^2} \| x_{k+1} - z \|^2 + \Phi(z).$$

(1.5)

According to Bayesian probability, (1.5) corresponds to denoising the image $x_{k+1}$ by a Gaussian denoiser with noise level $\sqrt{\lambda/\alpha}$. As a consequence, any Gaussian denoisers can be acted as a modular part to solve (1.2). To address this, we rewrite (1.5) by the following:

$$z_{k+1} = \text{Denoiser}(x_{k+1}, \sqrt{\lambda/\alpha}).$$

(1.6)

It is worth noting that, according to (1.5) and (1.6), the image prior $\Phi(\cdot)$ can be implicitly replaced by a denoiser prior. In this paper, we apply the proposed denoiser as a prior to generate a better performance.

In recent years, deep learning-based models have extensively emerged and achieved state-of-the-art restoration performance [4, 9, 15, 17, 19]. The SeaNet proposed in [6] consists of three subnets for single image super-resolution with the help of image soft edge. Liu et al. [18] proposed MWCNN for image restoration, which is a U-shaped network with DWT and IWT for downsampling and upsampling, respectively, and thus there is no information loss during subsampling. Both approaches achieved competitive performance in IR tasks.

To improve interpretability and effectively use the trained neural networks from various tasks, plug-and-play (PnP) is one of the choices to combine neural networks and prior knowledge of images with an optimization model. Zhang et al. [28, 29] developed the deep prior to handle the IR tasks, PnP. Specifically, they regarded the regularization term $\Phi(x)$ as a deep denoiser with the deep CNNs. The optimization problem (1.2) was solved by the half quadratic splitting (HQS) algorithm and divided into two subproblems, in which the solution of one of the problems is replaced by the deep CNN, which is the so-called deep denoiser.

Furthermore, the step (1.4) is usually termed a denoiser prior and conducted by a single CNN denoiser [31], which is trained specifically for a denoising prior and to replace solving (1.4) to exploit the advantages of CNN. Following this line, the PnP-based model has wide applications [10]. For example, Wu et al. [26] proposed a deep CNN-based PnP framework with MWCNN and has competitive performance in Cauchy noise removal. Zhao et al. [31] suggested a PnP model for image completion with a low rankness assumption. Fang and Zeng [7] applied the soft edge network [6] as a denoiser for image deblurring and denoising and gave a mathematical interpretation of the PnP-based model. Overall, the PnP-based framework has a promising performance.

Motivated by the advantages of the aforementioned PnP models, in this paper, we are going to apply them to the image inpainting problem for spherical signals. Precisely, for a spherical signal, with its partially observed samplings, a novel PnP model integrating spherical
framelet decomposition is proposed to restore the signal. The proposed model is based on low rank assumption under a directional spherical Haar tight framelet, which is designed for testing image texture. In addition, we exploit a newly designed deep convolutional neural network to be the PnP prior denoiser. The network inspired by [16, 12] employs two-stage encoder-decoder architecture, which is termed as Double-S2HaarNet. Under ground-truth supervision at each stage it provides progressive and improved denoising.

The rest of this paper is organized as follows. In section 2, the related works about spherical signal sampling and frame decomposition are reviewed. The proposed scheme and numerical algorithm are given in section 3. Numerical results including gray image and color image inpainting are listed in section 4. Section 5 concludes this paper.

2. Spherical signal sampling and frame decomposition. We employ a Haar tight framelet transform that was developed in [16]. Let $L_2(S^2)$ be a Hilbert space with inner product $\langle \cdot, \cdot \rangle$ and norm $\| \cdot \|$ defined by
\[
\langle f, g \rangle := \int_\Omega f(x)g(x)dx,
\]
\[
\|f\| = \left( \int_\Omega |f(x)|^2dx \right)^{\frac{1}{2}},
\]
where $f, g \in L_2(S^2)$ and $S^2 \in \mathbb{R}^3$ is the unit sphere. We call a countable collection $\{e_k\}_{k \in \Lambda} \subset L_2(S^2)$ a tight frame with frame bound $c$ if there exists a constant $c > 0$ such that
\[
f = \frac{1}{c} \sum_{k \in \Lambda} \langle f, e_k \rangle e_k \quad \forall f \in L_2(S^2).
\]

The frame decomposition is a transformation $\mathcal{F}$ given by
\[
\mathcal{F} : f \in L_2(S^2) \to \{ \langle f, e_i \rangle : e_i \in \{e_k\}_{k \in \Lambda} \}
\]
and the reconstruction $\mathcal{F}^*$ given by
\[
\mathcal{F}^* : \{ \langle f, e_i \rangle : e_i \in \{e_k\}_{k \in \Lambda} \} \to f \in L_2(S^2).
\]

A Haar tight frame on the sphere can be constructed based on a hierarchical partition.

Definition 2.1. Let $\mathbb{N}_0$ be a set of nonnegative integers. We call $\{\mathcal{B}_j\}_{j \in \mathbb{N}_0}$ a hierarchical partition of $S^2$ if the following three conditions are satisfied:

(a) Root property: $\mathcal{B}_0 = \{S^2\}$, and each $\mathcal{B}_j$ is a partition of $S^2$ having finitely many measurable sets with positive measures.

(b) Nested property: for any $j \in \mathbb{N}$ and any (child) set $R_1 \in \mathcal{B}_j$, there exists a (parent) set $R_0 \in \mathcal{B}_{j-1}$ such that $R_1 \subseteq R_0$. In other word, partition $\mathcal{B}_j$ is a refinement of the partition $\mathcal{B}_{j-1}$.

(c) Density property: the maximal diameters among the sets in $\mathcal{B}_j$ tend to zero as $j$ tends to infinity.
Denote \( \Lambda_j := [\ell_1] \times \cdots \times [\ell_j] \) to be an index set for the labeling sets in \( B_j \), where \( [N] = \{1, \ldots, N\} \) for any positive integer \( N \) and

\[
B_j = \{ R_{\vec{v}} \subseteq S^2, \; \vec{v} \in \Lambda_j \}.
\]

By the nested property, \( R_{(\vec{v},i)} \subseteq R_{\vec{v}} \) for \( \vec{v} \in \Lambda_{j-1} \) and \( i \in [\ell_j] \). Now, for each \( \vec{v} \in \Lambda_j \), define a Haar-type scaling function to be

\[
\phi_{\vec{v}} := \frac{\chi_{R_{\vec{v}}} \sqrt{|R_{\vec{v}}|}}{|R_{\vec{v}}|},
\]

and for some integer \( n_j \geq 1 \), Haar-type framelet functions to be

\[
\psi_{(\vec{v},k)} = \sum_{i \in [\ell_j]} a_{k,i}^{(\vec{v})} \phi_{(\vec{v},i)}, \quad k = 1, \ldots, n_j,
\]

where \( a_{k,i}^{(\vec{v})} \) is the \((k,i)\)-entry of some matrix \( A_{\vec{v}} \in \mathbb{R}^{n_j \times l_j} \). By setting proper matrices \( A_{\vec{v}} \), one can construct a Haar-type tight frame and develop its fast decomposition and reconstruction algorithms. The following corollary determines the framelet and algorithm we shall use.

**Corollary 2.2.** There exists a collection \( \{ \phi_{\vec{u}} \}_{\vec{u} \in \Lambda_L} \cup \{ \psi_{(\vec{v},k)} \}_{k \in [6], \vec{v} \in \Lambda_j, j \geq L} \subset L_2(S^2) \) determined by a hierarchical partition with each parent containing four children that forms a Haar tight frame with frame bound 1, and the corresponding operators \( \mathcal{F} \) and \( \mathcal{F}^* \) depend on the following matrix \( P \):

\[
P = \frac{1}{2} \begin{bmatrix}
1 & 1 & 1 & 1 \\
1 & -1 & 0 & 0 \\
1 & 0 & -1 & 0 \\
1 & 0 & 0 & -1 \\
0 & 1 & -1 & 0 \\
0 & 1 & 0 & -1 \\
0 & 0 & 1 & -1
\end{bmatrix}.
\]

As is well known, computers can only deal with discrete signals. To do spherical signal processing, we first need a proper way to discretize an analog signal. In this work, we take the discretization sampling method based on an area-regular partition of 2-sphere [16]. It was constructed through a bijective mapping and its rotations: \( T : [-1,1] \times [-1,1] \to S^2 \) defined by \( T(x,y) = \frac{(x,y,1)}{\sqrt{x^2 + y^2 + 1}} \). See Figure 1 for the illustration.

Then, for any given resolution \( J \geq 0 \), a 2-sphere can be divided into equal-area partitions; see Figure 2 for the illustration. This forms an algorithm for a hierarchical partition on the 2-sphere.

By taking the centers of the partition patches, the samplings of an analog signal can be distributed equivalently, which takes advantage over the traditional spherical coordinate discretization.

Based on the above discussion, any signal \( f \in L_2(S^2) \) is discretized to \( f \), which depends on a certain resolution \( J \). The discrete signal \( f \) is actually the set \( \{ f(\xi_i) : \xi_i \in S_i, S_i \in B_j, \bigcup_j S_i = S^2, S_j \cap S_k = \emptyset \; \forall \; j \neq k \} \). We assume that the dataset is defined on some resolution level
in the following and assume the sampling \( f \) of \( f \) is in \( \mathbb{R}^d \). Applying the discretization and Corollary 2.2, the spherical Haar framelet and fast framelet transform algorithms are exactly constructed.

With the help of the fast decomposition and reconstruction algorithms, it, on the one hand, allows our model to capture directional texture details. On the other hand, it can reduce the spatial footprint and granularity of convolutions.

3. The proposed model and algorithm. In this section, based on the aforementioned off-the-shelf spherical signal sampling and Haar-type framelets, to enhance the inpainting performance, we shall first improve the denoiser and then exploit a PnP model involving fast frame decomposition.

3.1. Improved denoiser. As mentioned above, the iteration (1.4) will be conducted by a denoiser. The performance of the denoiser will affect the resulting restoration. In [16], a CNN spherical denoising model, S2HaarNet, was developed and achieved a competitive performance. In the present paper, we further exploit a new spherical CNN (illustrated in Figure 3), which partly follows the infrastructure of the Double-Unet [12] and S2HaarNet [16] and incorporates the skip connections and spherical frame transformations. Thus we shall call it Double-S2HaarNet.

The new network consists of two feature encoder-decoder stages for which each one follows S2HaarNet. We then take ground-truth supervision at each stage for progressive and improved
denoising performance. We adopt the feature concatenation by combining the feature maps from the encoder path and decoder path, which can capture multiscale information and enrich feature representation for a better feature prediction. To bridge the two blocks, we concentrate the input and output of the first block and feed it into the second. Our model can also be readily extended to deal with color images by handling three channels independently.

For the designed models, we also present the computational cost. As we know, the indexes that are often used to measure the complexity of deep learning models include parameters, FLOPs (Floating-point Operations), and running time. More specifically, the parameters refer to the total number of parameters that need to be trained during model training, which is used to measure the computational space complexity. FLOPs is often used as an indirect measure of the speed of the neural network model. The complexity of the proposed networks S2HaarNet and Double-S2HaarNet are listed in Table 1.

### 3.2. Proposed PnP model

To develop a PnP model, besides the above pretrained denoiser, a proper design for a data fitting subproblem plays a crucial role as well. In this work, we attempt to propose a new data fitting operator to simultaneously exploit the strengths of the PnP model. In [31], data fitting was operated by using the tensor singular value decomposition and tensor nuclear norm, which promoted the low-rankness of the underlying tensor.

</tbody>
</table>
Motivated by such an idea, we instead utilize the tight frame decomposition in our data fitting and suggest the novel PnP model as follows:

\[
\min_x \| \mathcal{F} x \|_0 + \lambda \Phi(x)
\]
\[
s.t. \quad \mathcal{P}_\gamma(x) = \mathcal{P}_\gamma(g),
\]
where \( \mathcal{F} x \) is the coefficient of tight frame decomposition as mentioned in subsection 3.1, \( \Phi(x) \) is an implicit regularizer by plugging our denoising Double-S2HaarNet, \( \mathcal{P}_\gamma \) is a predefined observation operator, and \( \lambda \) is a positive parameter. The observation operator is defined with respect to a prior-given subset \( \gamma \subset [d] \), \( |\gamma| = m \leq d \), which refers to locations of known observation points. Precisely, for any signal \( x \in L_2(S^2) \) and its discretization \( x \in \mathbb{R}^d \), \( \mathcal{P}_\gamma(x) := O x \), where \( O \in \mathbb{R}^{d \times d} \) with the \( k \)-th row of \( O \) being the \( k \)-th one-hot row for \( k \in \gamma \) and the remaining rows being zero. In addition, we denote \( \mathcal{P}_\gamma(x) := (I - O)x \).

3.3. Implementation details. We apply the ADMM framework to solve the optimization problem. Notice that in practice it is more convenient to replace \( \| \cdot \|_0 \) by \( \| \cdot \|_1 \). Then we reformulate model (3.1) as

\[
\min_x \| y \|_1 + \lambda \Phi(z)
\]
\[
s.t. \quad \mathcal{P}_\gamma(x) = \mathcal{P}_\gamma(g), \quad y = \mathcal{F} x, \quad z = x.
\]

The augmented Lagrangian function of (3.2) is

\[
\mathcal{L}(x, y, z; \Lambda_1, \Lambda_2) = \| y \|_1 + \lambda \Phi(z) + \langle y - \mathcal{F} x, \Lambda_1 \rangle + \frac{\beta_1}{2} \| y - \mathcal{F} x \|^2 + \langle z - x, \Lambda_2 \rangle + \frac{\beta_2}{2} \| z - x \|^2
\]
\[
s.t. \quad \mathcal{P}_\gamma(x) = \mathcal{P}_\gamma(g),
\]
where \( \beta_1, \beta_2 > 0 \) are two penalty parameters and \( \Lambda_1, \Lambda_2 \) are the Lagrange multipliers. The ADMM iteration for solving (3.3) goes as follows:

\[
\left\{
\begin{array}{l}
y = \arg \min_y \| y \|_1 + \langle y - \mathcal{F} x, \Lambda_1 \rangle + \frac{\beta_1}{2} \| y - \mathcal{F} x \|^2, \\
z = \arg \min_y \lambda \Phi(z) + \langle z - x, \Lambda_2 \rangle + \frac{\beta_2}{2} \| z - x \|^2,
\end{array}
\right.
\]
\[
\left\{
\begin{array}{l}
x = \arg \min_z \frac{\beta_1}{2} \| y - \mathcal{F} x + \frac{\Lambda_1}{\beta_1} \|^2 + \langle z - x, \Lambda_2 \rangle + \frac{\beta_2}{2} \| z - x \|^2, \\
\end{array}
\right.
\]
\[
\begin{array}{l}
s.t. \quad \mathcal{P}_\gamma(x) = \mathcal{P}_\gamma(g), \\
\Lambda_1 = \Lambda_1 + (y - \mathcal{F} x), \\
\Lambda_2 = \Lambda_2 + (z - x).
\end{array}
\]

Next, we elaborate on how to solve these respective subproblems.

- The \( y \)-subproblem is written as

\[
y = \arg \min_y \| y \|_1 + \langle y - \mathcal{F} x, \Lambda_1 \rangle + \frac{\beta_1}{2} \| y - \mathcal{F} x \|^2
\]
\[
= \arg \min_y \| y \|_1 + \frac{\beta_1}{2} \left\| y - \mathcal{F} x + \frac{\Lambda_1}{\beta_1} \right\|^2.
\]
Then the solution of $y$ can be obtained by
\[
y = \text{shrink} \left( \mathcal{F} x - \frac{\Lambda_1}{\beta_1}, \frac{1}{\beta_1} \right)
\]
(3.6)
\[
y = \max \left( \frac{\| \mathcal{F} x - \frac{\Lambda_1}{\beta_1} \|_2 - \frac{1}{\beta_1}, 0 }{\| \mathcal{F} x - \frac{\Lambda_1}{\beta_1} \|} \right). 
\]
where the shrink operator is a soft shrinkage operator.

- The $z$-subproblem is written as
\[
z = \arg \min_z \lambda \Phi(z) + \langle z - x, \Lambda_2 \rangle + \frac{\beta_2}{2} \| z - x \|^2
\]
(3.7)
\[
z = \arg \min_z \lambda \Phi(z) + \frac{\beta_2}{2} \| z - x + \frac{\Lambda_2}{\beta_2} \|^2 . 
\]
According to Bayes rule, (3.7) corresponds to denoising the image $x - \Lambda_2/\beta_2$ by the CNN denoiser with noise level $\lambda/\beta_2$. To address this, we rewrite (3.7) as
\[
z = \text{Denoiser} \left( x - \frac{\Lambda_2}{\beta_2}, \sqrt{\frac{\lambda}{\beta_2}} \right).
\]
In this paper, we apply the Double-S2HaarNet as the denoiser.

- The $x$-subproblem is written as
\[
x = \arg \min_x \frac{\beta_1}{2} \left\| y - \mathcal{F} x + \frac{\Lambda_1}{\beta_1} \right\|^2 + \langle z - x, \Lambda_2 \rangle + \frac{\beta_2}{2} \| z - x \|^2
\]
(3.9)
\[
x = \arg \min_x \frac{\beta_1}{2} \left\| y - \mathcal{F} x + \frac{\Lambda_1}{\beta_1} \right\|^2 + \frac{\beta_2}{2} \| z - x + \frac{\Lambda_2}{\beta_2} \|^2 ,
\]
s.t. $\mathcal{P}_\gamma(x) = \mathcal{P}_\gamma(g)$.

By minimizing the $x$-subproblem, we have $1_\Omega(x) = 0$, i.e., $x \in \mathbb{S}$. Then the optimality condition of (3.9) is given by
\[
\beta_1 \mathcal{F}^* \left( \mathcal{F} x - y - \frac{\Lambda_1}{\beta_1} \right) + \beta_2 \left( x - z - \frac{\Lambda_2}{\beta_2} \right) = 0.
\]
(3.10)
Since $\mathcal{F}^* \mathcal{F} = I$, we obtain the following linear system:
\[
(\beta_1 + \beta_2) x = \beta_1 \mathcal{F}^* y + \beta_2 z + \mathcal{F}^* \Lambda_1 + \Lambda_2.
\]
(3.11)
Thus, the closed-form solution of the $x$-subproblem is given as $x^* = \mathcal{P}_\gamma(x^*) + (\mathcal{P}_{\gamma^*})(x^*)$:
\[
\begin{cases}
\mathcal{P}_\gamma(x^*) = \mathcal{P}_\gamma(g), \\
\mathcal{P}_{\gamma^*}(x^*) = \mathcal{P}_{\gamma^*} \left( \frac{\beta_1 \mathcal{F}^* y + \beta_2 z + \mathcal{F}^* \Lambda_1 + \Lambda_2}{\beta_1 + \beta_2} \right).
\end{cases}
\]
(3.12)
4. Experimental results. In this section, we present experimental results to verify the performance of the proposed model Double-S2HaarNetPnP in image inpainting. As aforementioned, we proposed a PnP model for the image inpainting task. The parameters of the optimization function (3.3) are set as $\lambda = 1$, $\beta_1 \in [0.1, 1]$ with step 0.1, $\beta_2 \in [1, 5]$ with step 1. For training Double-S2HaarNet, we use the ADAM algorithm and a minibatch size of 16. The learning rate decays exponentially from the beginning value 0.001 with a multiplicative factor 0.9 in 100 epochs. Weight decay is chosen to be 0.001. Since the contrast of greyscale images is relatively low, we present the visual effects of the image with color so that the image information can be displayed more clearly.

4.1. Datasets. The dataset for training CNN denoisers is produced by converting color images of Caltech101 [8] into grey ones and then conducting spherical sampling (defined in section 2). 7677 images are for training, and 1000 are for validation. For the testing, we take the dataset F-360iSOD [30], which contains 107 omnidirectional images. Additionally, we take five classical images as illustrated in Figure 4 for testing as well. Experiments for color images are conducted on RGB channels, respectively.

4.2. Evaluation metrics. To demonstrate the effectiveness of the proposed scheme, we test the images with random missing values, i.e., the missing ratio with 50%, 80%, 90%, 95%. With the built-in function in numpy, we use the command “numpy.random.rand” to generate random values of the same size as the input image. Then let the value greater than the missing ratio equal to 1 and less than the missing ratio equal to 0. Then we have the missing operator, with the function “numpy.multiply” mapping the missing operator and the ground truth image to the observed image. The peak signal-to-noise ratio (PSNR) and structural similarity index (SSIM) are used to evaluate the performance of the inpainting results. To be specific, with the reference $x$ and the obtained result $x^*$, the PSNR is defined as

$$
\text{PSNR}(x, x^*) = 20 \log_{10} \frac{255}{\| x^* - x \|},
$$

where $\| \cdot \|$ denotes a Frobenius norm. The SSIM is defined as

$$
\text{SSIM}(x, x^*) = \frac{(2\mu_x\mu_{x^*} + C_1)(2\sigma_{x\cdot x^*} + C_2)}{(\mu_x^2 + \mu_{x^*}^2 + C_1)(\sigma_x^2 + \sigma_{x^*}^2 + C_2)},
$$

where $\mu_x$, $\mu_{x^*}$ and $\sigma_x$, $\sigma_{x^*}$, $\sigma_{x\cdot x^*}$ are the mean and the standard deviation of $x$ and $x^*$, respectively. The positive constants $C_1$ and $C_2$ are used to avoid a null denominator, which are defaulted by the built-in ssim function.
### 4.3. Results

We make a detailed comparison of our method. More specifically, the methods with single net (S2HaarNet and DoubleS2HaarNet) and the methods with plug-and-play (S2HaarNetPnP and DoubleS2HaarNetPnP) are compared. First, the three datasets are tested. The results of datasets F6, F7, and F8 are listed in Table 2, from which we know that the proposed methods are robust in different degradation. For example, when the missing ratio is from 50% up to 95%, our methods always have competitive restoration results. Besides, the results based on the PnP approach are better than the one with only CNN, which also illustrate the effectiveness of the proposed PnP scheme. Moreover, the testing of two different datasets and different combinations of the proposed model also gives a strong validity to our scheme. On the other hand, five grey images are also tested in this paper. We list the numerical results in Table 3, from which the PnP-based models also have better restoration results.

The visual results are present in Figures 5–8 with missing ratios 50%, 80%, 90%, 95%, respectively. Figure 5(a) is the observed image with a low missing ratio (50%). As we can see from the results (b)–(e), most of the objects in the image are recovered. However, with detailed observation, we know that the PnP-based methods have more competitive performance. With the missing ratio up to 80%, there are some outlines of the original image that can be seen in Figure 6(a). It turns out that the results of the S2HaarNet and Double-S2HaarNet have quite satisfactory results. As the PnP is applied in (b) and (d), respectively, the results of inpainting are greatly improved. For the low sample ratio, from Figures 7(a) and 8(a), the details of the image have almost disappeared. With this low observation, our models also can recover the images with good quality. The above visual results demonstrate again the robustness and effectiveness of the proposed inpainting models.

The experiments on color images are also conducted in Figures 9–12, which illustrate the good generalization of our model to color images. Note that our results are slightly

oversmoothed for lower sample rates, such as 95%. Figure 12 shows that, in contrast to other results, our solutions can better restore the structures of images, which is consistent with the results of the majority of PnP-based works.

4.4. Ablation experiments. In this section, to analyze the improvement effect of introducing framelet transforms in image inpainting tasks, the following three variants of our model are designed for comparison: (a) random filters for constructing framelets, which is different from specifically designed directional framelets with respect to matrix (2.3); (b) max-pooling for downsampling and bilinear interpolation for upsampling; (c) average pooling for downsampling and bilinear interpolation for upsampling. The comparison results are illustrated in Table 4, which shows the advantages by introducing framelet transforms, especially for the case of high inpainting rates.

5. Conclusion and further remarks. In this work, we presented a novel model, the Double-S2HaarNetPnP model, for image inpainting. We remark that (a) low-rank framelet coefficient regularizer is introduced to learn; (b) a new denoiser Double-S2HaarNet for spherical image inpainting is proposed, and in the experiments it is powerful for the inpainting task with...

are to develop a proper hierarchical partition of a manifold and explore the corresponding convolution calculation. With them, the proposed model can be further generalized to other manifolds.
Table 4
Average and variance inpainting results of Double-S2HaarNet variants with PSNR/SSIM on F-360iSOD. In Fx, x = 6, 7, 8, represents the resolution level.
