

Spherical Image Inpainting with Frame Transformation and Data-driven Prior Deep Networks *

Jianfei Li[†], Chaoyan Huang[‡], Raymond Chan[§], Han Feng[¶], Michael Ng^{||}, and Tiejong Zeng[#]

Abstract. Spherical image processing has been widely applied in many important fields, such as omnidirectional vision for autonomous cars, global climate modelling, and medical imaging. It is non-trivial to extend an algorithm developed for flat images to the spherical ones. In this work, we focus on the challenging task of spherical image inpainting with deep learning-based regularizer. Instead of a naive application of existing models for planar images, we employ a fast directional spherical Haar framelet transform and develop a novel optimization framework based on a sparsity assumption of the framelet transform. Furthermore, by employing progressive encoder-decoder architecture, a new and better-performed deep CNN denoiser is carefully designed and works as an implicit regularizer. Finally, we use a plug-and-play method to handle the proposed optimization model, which can be implemented efficiently by training the CNN denoiser prior. Numerical experiments are conducted and show that the proposed algorithms can greatly recover damaged spherical images and achieve the best performance over purely using deep learning denoiser and plug-and-play model.

Key words. Spherical image inpainting, deep CNN, plug and play

MSC codes. 68Q25, 68R10, 68U05

1. Introduction. In practical problems, a large amount of data comes in the form of spherical images, such as from cosmology [20], astrophysics [22], geophysics [1, 23], neuroscience [21], and omnidirectional AR/VR field [2, 27], where images are naturally defined on the 2D spherical surface. Due to the storage bottleneck and observation being costly and infeasible, these spherical images (signals) usually contain very limited pixels (observed data), especially if the observation scales involved are large. Therefore, repairing missing or damaged parts is a fundamental yet challenging task in spherical image processing. Apparently, spherical images take a different inherent domain than planar images in 2D in terms of symmetries,

coordinate systems, and translates, which demand special processing methods. In this paper, we are concerned with spherical image restoration, which can further serve as a preliminary for subsequent tasks, like object recognition and segmentation. Mathematically, it aims to estimate \mathbf{x} from observation \mathbf{y} for the following model

$$(1.1) \quad \mathbf{y} = T(\mathbf{x}) + \varepsilon,$$

where T is a degradation operator, ε is assumed to be the additive noise. Different degradation operations correspond to different image restoration (IR) tasks [13, 14]. Typically, the IR task would be image denoising when T is an identity operation, image deblurring when T is a two-dimensional convolution operation, image super-resolution when T is a composite operation of convolution and down-sampling, color image demosaicing when T is a color filter array (CFA) masking operation, and image inpainting when T is the orthogonal projection onto the linear space of matrices. In this paper, we proposed a general model for spherical image inpainting with a new denoiser.

Regarding the degradation equation (1.1), the IR task model can be solved through the following optimization,

$$(1.2) \quad \hat{\mathbf{x}} = \arg \min_{\mathbf{x}} \|\mathbf{y} - T(\mathbf{x})\| + \lambda \Phi(\mathbf{x}),$$

where the first term is the data fitting with $\|\cdot\|$ usually chosen to be the Frobenius norm, the second term $\Phi(\cdot)$ is an operator playing the role of regularity, and λ is a positive trade-off parameter. With the aid of the half quadratic splitting (HQS) algorithm, by introducing an auxiliary variable, the optimization problem (1.2) can be addressed by iteratively solving the following subproblems

$$(1.3) \quad \mathbf{x}_k = \arg \min_{\mathbf{x}} \|\mathbf{y} - T(\mathbf{x})\|^2 + \alpha \|\mathbf{x} - \mathbf{z}_{k-1}\|^2,$$

$$(1.4) \quad \mathbf{z}_k = \arg \min_{\mathbf{z}} \alpha \|\mathbf{z} - \mathbf{x}_k\|^2 + \lambda \Phi(\mathbf{z}).$$

Here α will be set accordingly to specific problems. Equation (1.3) is usually interpreted as the data fitting subproblem and (1.4) as the regularization subproblem. Many research efforts have been devoted to this hot topic and achieved extensive improvements [3, 5, 11, 24, 25].

As one can see, the fidelity term and regularization term are decoupled into two individual subproblems. Specifically, the fidelity term is associated with a quadratic regularized least-squares problem (i.e., Eq. (1.3)) which has various fast solutions for different degradation matrices. The regularization term is involved in Eq. (1.4), which can be rewritten as

$$(1.5) \quad \mathbf{z}_{k+1} = \arg \min_{\mathbf{z}} \frac{1}{2(\sqrt{\lambda/\alpha})^2} \|\mathbf{x}_{k+1} - \mathbf{z}\|^2 + \Phi(\mathbf{z}).$$

According to Bayesian probability, Eq. (1.5) corresponds to denoising the image \mathbf{x}_{k+1} by a Gaussian denoiser with noise level $\sqrt{\lambda/\alpha}$. As a consequence, any Gaussian denoisers can be acted as a modular part to solve Eq. (1.2). To address this, we rewrite Eq. (1.5) by following

$$(1.6) \quad \mathbf{z}_{k+1} = \text{Denoiser} \left(\mathbf{x}_{k+1}, \sqrt{\lambda/\alpha} \right).$$

63 It is worth noting that, according to Eqs. (1.5) and (3.7), the image prior $\Phi(\cdot)$ can be implicitly
64 replaced by a denoiser prior. In this paper, we apply the proposed denoiser as prior to generate
65 a better performance.

66 In recent years, deep learning-based models have extensively emerged and achieved state-of-
67 the-art restoration performance [4, 9, 15, 17, 19]. The SeaNet proposed in [6] consists of three
68 sub-nets for single image super-resolution with the help of image soft edge. Liu et al. [18]
69 proposed MWCNN for image restoration, which is a U shape network with DWT and IWT
70 for downsampling and upsampling, respectively, and thus there is no information loss during
71 subsampling. Both approaches achieved competitive performance in IR tasks.

72 To improve interpretability and effectively use the trained neural networks from various tasks,
73 Plug and Play is one of the choices to combine neural networks and prior knowledge of images
74 with an optimization model. Zhang et al. [28, 29] developed the deep prior to handling the IR
75 tasks, named plug-and-play (PnP). Specifically, they regarded the regularization term $\Phi(x)$ as
76 a deep denoiser with the deep CNNs. The optimization problem (1.2) was solved by the half
77 quadratic splitting (HQS) algorithm and divided into two subproblems, in which the solution
78 of one of the problems is replaced by the deep CNN, which is the so-called deep denoiser.

79 Furthermore, the term (1.4) is usually termed as denoiser prior and conducted by a single
80 CNN denoiser [31], which is trained specifically for denoising prior and to replace solving
81 (1.4) to exploit the advantages of CNN. Following this line, the PnP-based model has wide
82 applications [10]. For example, Wu et al. [26] proposed a deep CNN-based PnP framework
83 with MWCNN and has competitive performance in Cauchy noise removal. Zhao et al. [31]
84 suggested a PnP model for image completion with a low rankness assumption. Fang and Zeng
85 [7] applied the soft edge network [6] as a denoiser for image deblurring and denoising and gave
86 a mathematical interpretation of the PnP-based model. Overall, the PnP-based framework
87 has a promising performance.

88 Motivated by the advantages of the aforementioned PnP models, in this paper, we are going
89 to apply them to image inpainting problem for spherical signals. Precisely, for a spherical
90 signal, with its partially observed samplings, a novel PnP model integrating spherical framelet
91 decomposition is proposed to restore the signal. The proposed model is based on low rank
92 assumption under directional spherical Haar tight framelet, which is designed for testing image
93 texture. In addition, we exploit a newly designed deep convolutional neural network to be
94 the plug-and-play prior denoiser. The network inspired by [16] and [12] employs two-stage
95 encoder-decoder architecture, which is termed as Double-S2HaarNet. Under ground-truth
96 supervision at each stage it provides progressive and improved denoising.

97 The rest of this paper is organized as follows. In section 2, the related works about spherical
98 signal sampling and frame decomposition are reviewed. The proposed scheme and numerical
99 algorithm are given in section 3. Numerical results including gray image and color image
100 inpainting are listed in section 4. Section 5 concludes this paper.

101 **2. Spherical signal sampling and frame decomposition.** We employ a Haar tight framelet
102 transform that developed in [16]. Let $L_2(\mathbb{S}^2)$ be a Hilbert space with inner product $\langle \cdot, \cdot \rangle$ and

103 norm $\|\cdot\|$ defined by

$$\begin{aligned} 104 \quad \langle f, g \rangle &:= \int_{\Omega} f(x)g(x)dx, \\ 105 \quad \|f\| &= \left(\int_{\Omega} |f(x)|^2 dx \right)^{\frac{1}{2}}, \\ 106 \end{aligned}$$

107 where $f, g \in L_2(\mathbb{S}^2)$ and $\mathbb{S}^2 \in \mathbb{R}^3$ is the unit sphere. We call a countable collection $\{e_k\}_{k \in \Lambda} \subset$
 108 $L_2(\mathbb{S}^2)$ a *tight frame* with frame bound c if there exists a constant $c > 0$ such that

$$109 \quad f = \frac{1}{c} \sum_{k \in \Lambda} \langle f, e_k \rangle e_k \quad \forall f \in L_2(\mathbb{S}^2). \\ 110$$

111 The frame decomposition is a transformation \mathcal{F} given by

$$112 \quad \mathcal{F} : f \in L_2(\mathbb{S}^2) \rightarrow \{ \langle f, e_i \rangle : e_i \in \{e_k\}_{k \in \Lambda} \}, \\ 113$$

114 and the reconstruction \mathcal{F}^*

$$115 \quad \mathcal{F}^* : \{ \langle f, e_i \rangle : e_i \in \{e_k\}_{k \in \Lambda} \} \rightarrow f \in L_2(\mathbb{S}^2). \\ 116$$

117 A Haar tight frame on the sphere can be constructed based on a hierarchical partition.

118 **Definition 2.1.** Let \mathbb{N}_0 be a set of nonnegative integers. We call $\{\mathcal{B}_j\}_{j \in \mathbb{N}_0}$ a hierarchical parti-
 119 tion of \mathbb{S}^2 if the following three conditions are satisfied:

- 120 a) *Root property:* $\mathcal{B}_0 = \{\mathbb{S}^2\}$ and each \mathcal{B}_j is a partition of \mathbb{S}^2 having finitely many mea-
 121 surable sets with positive measures.
- 122 b) *Nested property:* for any $j \in \mathbb{N}$ and any (child) set $R_1 \in \mathcal{B}_j$, there exists a (parent)
 123 set $R_0 \in \mathcal{B}_{j-1}$ such that $R_1 \subseteq R_0$. In other word, partition \mathcal{B}_j is a refinement of the
 124 partition \mathcal{B}_{j-1} .
- 125 c) *Density property:* the maximal diameters among the sets in \mathcal{B}_j tend to zero as j tends
 126 to infinity.

127 Denote $\Lambda_j := [\ell_1] \times \cdots \times [\ell_j]$ to be an index set for the labeling sets in \mathcal{B}_j , where $[N] =$
 128 $\{1, \dots, N\}$ for any positive integer N and

$$129 \quad \mathcal{B}_j = \{R_{\vec{v}} \subseteq \mathbb{S}^2, \vec{v} \in \Lambda_j\}.$$

130 By the nested property, $R_{(\vec{v}, i)} \subseteq R_{\vec{v}}$ for $\vec{v} \in \Lambda_{j-1}$ and $i \in [\ell_j]$. Now, for each $\vec{v} \in \Lambda_j$, define a
 131 Haar-type scaling function to be

$$132 \quad (2.1) \quad \phi_{\vec{v}} := \frac{\chi_{R_{\vec{v}}}}{\sqrt{|R_{\vec{v}}|}},$$

133 and for some integer $n_j \geq 1$, n_j Haar-type framelet functions to be

$$134 \quad (2.2) \quad \psi_{(\vec{v},k)} = \sum_{i \in [\ell_j]} a_{k,i}^{(\vec{v})} \phi_{(\vec{v},i)}, \quad k = 1, \dots, n_j,$$

135 where $a_{k,i}^{(\vec{v})}$ is the (k, i) -entry of some matrix $\mathbf{A}_{\vec{v}} \in \mathbb{R}^{n_j \times \ell_j}$. By setting proper matrices $\mathbf{A}_{\vec{v}}$, one
 136 can construct a Haar-type tight frame and develop its fast decomposition and reconstruction
 137 algorithms. The following corollary determines the framelet and algorithm we shall use.

138 **Corollary 2.2.** *There exists a collection $\{\phi_{\vec{u}}\}_{\vec{u} \in \Lambda_L} \cup \{\psi_{(\vec{v},k)}, k \in [6]\}_{j \geq L, \vec{v} \in \Lambda_j} \subset L_2(\mathbb{S}^2)$ deter-*
 139 *mined by a hierarchical partition with each parent containing four children that forms a Haar*
 140 *tight frame with frame bound 1, and the corresponding operators \mathcal{F} and \mathcal{F}^* depend on the*
 141 *following matrix P*

$$142 \quad (2.3) \quad P = \frac{1}{2} \begin{bmatrix} 1 & 1 & 1 & 1 \\ 1 & -1 & 0 & 0 \\ 1 & 0 & -1 & 0 \\ 1 & 0 & 0 & -1 \\ 0 & 1 & -1 & 0 \\ 0 & 1 & 0 & -1 \\ 0 & 0 & 1 & -1 \end{bmatrix}.$$

144 As it is well known, computers can only deal with discrete signals. To do spherical signal
 145 processing, we first need a proper way to discretize an analog signal. In this work, we take
 146 the discretization sampling method based on an area-regular partition of 2-sphere [16]. It was
 147 constructed through a bijective mapping and its rotations: $T : [-1, 1] \times [-1, 1] \rightarrow \mathbb{S}^2$ defined
 148 by $T(x, y) = \frac{(x, y, 1)}{\sqrt{x^2 + y^2 + 1}}$. See Figure 1 below for the illustration.

Figure 1. Visualization of mapping T which maps a square to a spherical cap.

149 Then for any given resolution $J \geq 0$, a 2-sphere can be divided into equal-area partitions, see
 150 Figure 2 for illustration. This forms an algorithm for a hierarchical partition on the 2-sphere.

151 By taking the centers of the partition patches, the samplings of an analog signal can be
 152 distributed equivalently, which takes advantage over the traditional spherical coordinates dis-
 153 cretization.

154 Based on the above discussion, any signal $f \in L_2(\mathbb{S}^2)$ is discretized to \mathbf{f} , which depends on a
 155 certain resolution J . The discrete signal \mathbf{f} is actually the set $\{f(\xi_i) : \xi_i \in S_i, S_i \in \mathcal{B}_j, \bigcup_i S_i =$

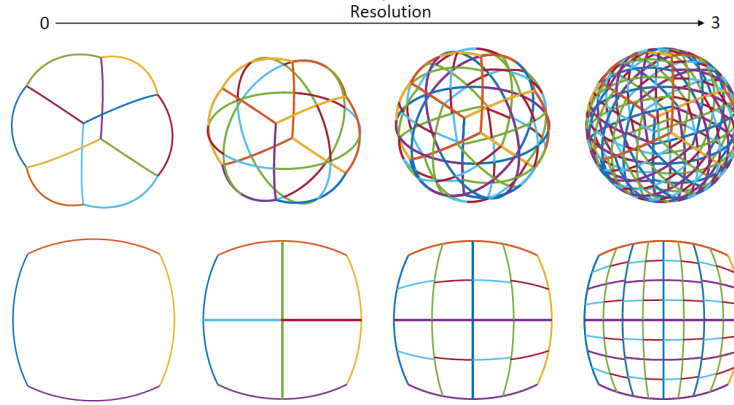

Figure 2. Partition Process.

156 $\mathbb{S}^2, S_j \cap S_k = \emptyset, \forall j \neq k$. We assume that the dataset is defined on some resolution level
 157 in the following and assume the sampling \mathbf{f} of f is in \mathbb{R}^d . Applying the discretization and
 158 Corollary 2.2, the spherical Haar framelet and fast framelet transform algorithm are exactly
 159 constructed.

160 With the help of the fast decomposition and reconstruction algorithms, it, on the one hand,
 161 allows our model to capture directional texture details. On the other hand, it can reduce the
 162 spatial footprint and granularity of convolutions.

163 **3. The proposed model and algorithm.** In this section, based on the aforementioned
 164 off-the-shelf spherical signal sampling and Haar-type framelets, to enhance the inpainting
 165 performance, we shall first improve the denoiser and then exploit a plug-and-play model
 166 involving fast frame decomposition.

167 **3.1. Improved Denoiser.** As mentioned above, the iteration (1.4) will be conducted by
 168 a denoiser. The performance of the denoiser will affect the resulting restoration. In [16],
 169 a CNN spherical denoising model, S2HaarNet, was developed and achieved a competitive
 170 performance. In the present paper, we further exploit a new spherical CNN (illustrated in
 171 Figure 3), which partly follows the infrastructure of the Double-Unet [12] and S2HaarNet [16],
 172 and incorporates the skip connections and spherical frame transformations. Thus we shall call
 173 it Double-S2HaarNet. The new network consists of two feature encoder-decoder stages for
 174 which each one follows S2HaarNet. We then take ground-truth supervision at each stage
 175 for progressive and improved denoising performance. We adopt the feature concatenation
 176 by combining the feature maps from the encoder path and decoder path, which can capture
 177 multi-scale information and enrich feature representation for a better feature prediction. To
 178 bridge the two blocks, we concentrate the input and output of the first block and feed it into
 179 the second. Our model can also be readily extended to deal with color images by handling
 180 three channels independently. For the designed models, we also present the computational
 181 cost. As we know that the indexes that are often used to measure the complexity of deep
 182 learning models include parameters, FLOPs (Floating-point Operations), and running time.

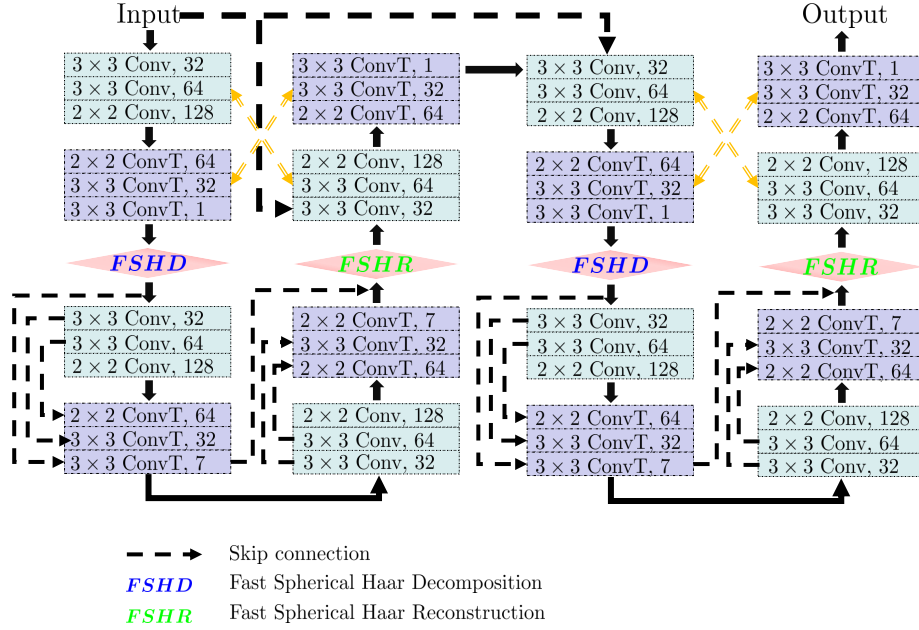

Figure 3. Double-S2HaarNet.

183 More specifically, the parameters refer to the total number of parameters that need to be
 184 trained during model training, which is used to measure the computational space complexity.
 185 FLOPs is often used as an indirect measure of the speed of the neural network model. The
 186 complexity of the proposed networks S2HaarNet and Double-S2HaarNet are listed in Table 1.

Table 1

The complexity (parameters (in MB), Flops (in GB), running times (in seconds)) of the proposed models.

Methods	Parameters	Flops	Running time
S2HaarNet	0.02MB	5.30G	0.0020s
Double-S2HaarNet	0.63MB	199.45G	0.1310s

187

188 **3.2. Proposed PnP model.** To develop a PnP model, besides the above pre-trained de-
 189 noiser, a proper design for data fitting subproblem plays a crucial role as well. In this work,
 190 we attempt to propose a new data fitting operator to simultaneously exploit the strengths of
 191 the PnP model. In [31], data fitting was operated by using the tensor singular value decom-
 192 position and tensor nuclear norm, which promoted the low-rankness of the underlying tensor.
 193 Motivated by such an idea, we instead utilize the tight frame decomposition in our data fitting

194 and suggest the novel PnP model as follows:

$$195 \quad (3.1) \quad \begin{aligned} & \min_{\mathbf{x}} \|\mathcal{F}\mathbf{x}\|_0 + \lambda\Phi(\mathbf{x}) \\ & \text{s.t. } \mathcal{P}_\gamma(\mathbf{x}) = \mathcal{P}_\gamma(\mathbf{g}), \end{aligned}$$

196 where $\mathcal{F}\mathbf{x}$ is the coefficients of tight frame decomposition as mentioned in subsection 3.1,
 197 $\Phi(\mathbf{x})$ is an implicit regularizer by plugging our denoising Double-S2HaarNet, \mathcal{P}_γ is a pre-
 198 defined observation operator, and λ is a positive parameter. The observation operator is
 199 defined with respect to a prior-given subset $\gamma \subset [d]$, $|\gamma| = m \leq d$, which refers to locations of
 200 known observation points. Precisely, for any signal $x \in L_2(\mathbb{S}^2)$ and its discretization $\mathbf{x} \in \mathbb{R}^d$,
 201 $\mathcal{P}_\gamma(\mathbf{x}) := \mathbf{O}\mathbf{x}$, where $\mathbf{O} \in \mathbb{R}^{d \times d}$ with the k th row of \mathbf{O} being the k th one-hot row for $k \in \gamma$
 202 and the remaining rows being zero. In addition, we denote $\mathcal{P}_{\gamma^c}(\mathbf{x}) := (\mathbf{I} - \mathbf{O})\mathbf{x}$.

203 **3.3. Implementation Details.** We apply ADMM framework to solve the optimization
 204 problem. Notice that in practice, it is more convenient to replace $\|\cdot\|_0$ by $\|\cdot\|_1$. Then we
 205 reformulate model (3.1) as

$$206 \quad (3.2) \quad \begin{aligned} & \min_{\mathbf{x}, \mathbf{y}, \mathbf{z}} \|\mathbf{y}\|_1 + \lambda\Phi(\mathbf{z}) \\ & \text{s.t. } \mathcal{P}_\gamma(\mathbf{x}) = \mathcal{P}_\gamma(\mathbf{g}), \mathbf{y} = \mathcal{F}\mathbf{x}, \mathbf{z} = \mathbf{x}. \end{aligned}$$

207 The augmented Lagrangian function of (3.2) is

$$208 \quad (3.3) \quad \begin{aligned} \mathcal{L}(\mathbf{x}, \mathbf{y}, \mathbf{z}; \Lambda_1, \Lambda_2) &= \|\mathbf{y}\|_1 + \lambda\Phi(\mathbf{z}) + \langle \mathbf{y} - \mathcal{F}\mathbf{x}, \Lambda_1 \rangle + \frac{\beta_1}{2} \|\mathbf{y} - \mathcal{F}\mathbf{x}\|^2 + \langle \mathbf{z} - \mathbf{x}, \Lambda_2 \rangle + \frac{\beta_2}{2} \|\mathbf{z} - \mathbf{x}\|^2, \\ & \text{s.t. } \mathcal{P}_\Gamma(\mathbf{x}) = \mathcal{P}_\Gamma(\mathbf{g}), \end{aligned}$$

209 where $\beta_1, \beta_2 > 0$ are two penalty parameters and Λ_1, Λ_2 are the Lagrange multipliers. The
 210 ADMM iteration for solving (3.3) goes as follows,

$$211 \quad (3.4) \quad \begin{cases} \mathbf{y} = \arg \min_{\mathbf{y}} \|\mathbf{y}\|_1 + \langle \mathbf{y} - \mathcal{F}\mathbf{x}, \Lambda_1 \rangle + \frac{\beta_1}{2} \|\mathbf{y} - \mathcal{F}\mathbf{x}\|^2, \\ \mathbf{z} = \arg \min_{\mathbf{z}} \lambda\Phi(\mathbf{z}) + \langle \mathbf{z} - \mathbf{x}, \Lambda_2 \rangle + \frac{\beta_2}{2} \|\mathbf{z} - \mathbf{x}\|^2, \\ \mathbf{x} = \arg \min_{\mathbf{x}} \frac{\beta_1}{2} \|\mathbf{y} - \mathcal{F}\mathbf{x} + \frac{\Lambda_1}{\beta_1}\|^2 + \langle \mathbf{z} - \mathbf{x}, \Lambda_2 \rangle + \frac{\beta_2}{2} \|\mathbf{z} - \mathbf{x}\|^2, \\ \text{s.t. } \mathcal{P}_\gamma(\mathbf{x}) = \mathcal{P}_\gamma(\mathbf{g}), \\ \Lambda_1 = \Lambda_1 + (\mathbf{y} - \mathcal{F}\mathbf{x}), \\ \Lambda_2 = \Lambda_2 + (\mathbf{z} - \mathbf{x}). \end{cases}$$

212 Next, we elaborate on how to solve these subproblems respectively.

213 • The \mathbf{y} -subproblem is written as

$$214 \quad (3.5) \quad \begin{aligned} \mathbf{y} &= \arg \min_{\mathbf{y}} \|\mathbf{y}\|_1 + \langle \mathbf{y} - \mathcal{F}\mathbf{x}, \Lambda_1 \rangle + \frac{\beta_1}{2} \|\mathbf{y} - \mathcal{F}\mathbf{x}\|^2 \\ &= \arg \min_{\mathbf{y}} \|\mathbf{y}\|_1 + \frac{\beta_1}{2} \left\| \mathbf{y} - \mathcal{F}\mathbf{x} + \frac{\Lambda_1}{\beta_1} \right\|^2. \end{aligned}$$

215 Then the solution of \mathbf{y} can be obtained by

$$\begin{aligned}
 \mathbf{y} &= \text{shrink} \left(\mathcal{F}\mathbf{x} - \frac{\Lambda_1}{\beta_1}, \frac{1}{\beta_1} \right) \\
 &= \max \left(\left\| \mathcal{F}\mathbf{x} - \frac{\Lambda_1}{\beta_1} \right\|_2 - \frac{1}{\beta_1}, 0 \right) \frac{\mathcal{F}\mathbf{x} - \frac{\Lambda_1}{\beta_1}}{\left\| \mathcal{F}\mathbf{x} - \frac{\Lambda_1}{\beta_1} \right\|},
 \end{aligned}
 \tag{3.6}$$

217 where the shrink operator is a soft shrinkage operator.

218 • The \mathbf{z} -subproblem is written as

$$\begin{aligned}
 \mathbf{z} &= \arg \min_{\mathbf{z}} \lambda \Phi(\mathbf{z}) + \langle \mathbf{z} - \mathbf{x}, \Lambda_2 \rangle + \frac{\beta_2}{2} \|\mathbf{z} - \mathbf{x}\|^2 \\
 &= \arg \min_{\mathbf{z}} \lambda \Phi(\mathbf{z}) + \frac{\beta_2}{2} \left\| \mathbf{z} - \mathbf{x} + \frac{\Lambda_2}{\beta_2} \right\|^2,
 \end{aligned}
 \tag{3.7}$$

220 According to Bayes rule, Eq. (3.7) corresponds to denoising the image $\mathbf{x} - \Lambda_2/\beta_2$ by
 221 the CNN denoiser with noise level λ/β_2 . To address this, we rewrite Eq. (3.7) as

$$\mathbf{z} = \text{Denoiser} \left(\mathbf{x} - \frac{\Lambda_2}{\beta_2}, \sqrt{\frac{\lambda}{\beta_2}} \right).
 \tag{3.8}$$

223 In this paper, we apply the Double-S2HaarNet as the denoiser.

224 • The \mathbf{x} -subproblem is written as

$$\begin{aligned}
 \mathbf{x} &= \arg \min_{\mathbf{x}} \frac{\beta_1}{2} \left\| \mathbf{y} - \mathcal{F}\mathbf{x} + \frac{\Lambda_1}{\beta_1} \right\|^2 + \langle \mathbf{z} - \mathbf{x}, \Lambda_2 \rangle + \frac{\beta_2}{2} \|\mathbf{z} - \mathbf{x}\|^2 \\
 &= \arg \min_{\mathbf{x}} \frac{\beta_1}{2} \left\| \mathbf{y} - \mathcal{F}\mathbf{x} + \frac{\Lambda_1}{\beta_1} \right\|^2 + \frac{\beta_2}{2} \left\| \mathbf{z} - \mathbf{x} + \frac{\Lambda_2}{\beta_2} \right\|^2. \\
 &\text{s.t. } \mathcal{P}_\gamma(\mathbf{x}) = \mathcal{P}_\gamma(\mathbf{g}),
 \end{aligned}
 \tag{3.9}$$

226 By minimizing the \mathbf{x} -subproblem, we have $\mathbf{1}_\Omega(\mathbf{x}) = 0$, i.e., $\mathbf{x} \in \mathbb{S}$. Then optimality
 227 condition of (3.9) is given by

$$\beta_1 \mathcal{F}^* \left(\mathcal{F}\mathbf{x} - \mathbf{y} - \frac{\Lambda_1}{\beta_1} \right) + \beta_2 \left(\mathbf{x} - \mathbf{z} - \frac{\Lambda_2}{\beta_2} \right) = 0.
 \tag{3.10}$$

229 Since $\mathcal{F}^* \mathcal{F} = I$, we obtain the following linear system,

$$(\beta_1 + \beta_2) \mathbf{x} = \beta_1 \mathcal{F}^* \mathbf{y} + \beta_2 \mathbf{z} + \mathcal{F}^* \Lambda_1 + \Lambda_2.
 \tag{3.11}$$

231 Thus, the closed-form solution of \mathbf{x} -subproblem is given as $\mathbf{x}^* = \mathcal{P}_\gamma(\mathbf{x}^*) + (\mathcal{P}_{\gamma^c})(\mathbf{x}^*)$:

$$\begin{cases} \mathcal{P}_\gamma(\mathbf{x}^*) = \mathcal{P}_\gamma(\mathbf{g}), \\ \mathcal{P}_{\gamma^c}(\mathbf{x}^*) = \mathcal{P}_{\gamma^c} \left(\frac{\beta_1 \mathcal{F}^* \mathbf{y} + \beta_2 \mathbf{z} + \mathcal{F}^* \Lambda_1 + \Lambda_2}{\beta_1 + \beta_2} \right). \end{cases}
 \tag{3.12}$$

234 **4. Experimental results.** In this section, we present experimental results to verify the
 235 performance of the proposed model Double-S2HaarNetPnP in image inpainting. As afore-
 236 mentioned, we proposed a plug-and-play model for the image inpainting task. The parameter
 237 of the optimization function (3.3) are set as $\lambda = 1$, $\beta_1 \in [0.1, 1]$ with step 0.1, $\beta_2 \in [1, 5]$ with
 238 step 1. For training Double-S2HaarNet, we use the ADAM algorithm and a mini-batch size
 239 of 16. The learning rate decays exponentially from the beginning value 0.001 with a multi-
 240 plicative factor 0.9 in 100 epochs. Weight decay is chosen to be 0.001. Since the contrast of
 241 grayscale images is relatively low, we present the visual effects of the image with color so that
 242 the image information can be displayed more clearly.

243 **4.1. Datasets.** The dataset for training CNN denoisers is produced by converting color
 244 images of Caltech101 [8] into grey ones and then conducting spherical sampling (defined in
 245 section 2). 7677 images are for training and 1000 are for validation. For the testing, we take
 246 the dataset F-360iSOD [30] which contains 107 omnidirectional images. Additionally, we take
 247 five classical images as illustrated in Figure 4 for testing as well. Experiments for color images
 248 are conducted on RGB channels, respectively.

Figure 5. The inpainting results (PSNR (dB)/SSIM) with random missing ratio 50%. (a) the degraded image; the recovered results of (b) Haar network only; (c) plug and play with Haar network; (d) Double-S2Haar network only; (e) plug and play with Double-S2Haar network; (f) the original image.

249 **4.2. Evaluation metrics.** To demonstrate the effectiveness of the proposed scheme, we
 250 test the images with random missing values, i.e., the missing ratio with 50%, 80%, 90%, 95%.
 251 With the built-in function in numpy, we use the command ‘numpy.random.rand’ to generate
 252 random values of the same size as the input image. Then let the value greater than the missing
 253 ratio equal to 1 and less than the missing ratio equal to 0. Then we have the missing operator,
 254 with the function ‘numpy.multiply’ mapping the missing operator and the ground truth image
 255 to the observed image. The peak signal-to-noise ratio (PSNR) and structural similarity index
 256 (SSIM) are used to evaluate the performance of the inpainting results. To be specific, with
 257 the reference x and the obtained result x^* , the PSNR is defined as

$$258 \quad (4.1) \quad \text{PSNR}(x, x^*) = 20 \log_{10} \frac{255}{\frac{1}{mn} \|x^* - x\|},$$

259 where $\|\cdot\|$ denotes a Frobenius norm. The SSIM is defined as

$$260 \quad (4.2) \quad \text{SSIM}(x, x^*) = \frac{(2\mu_x\mu_{x^*} + C_1)(2\sigma_{xx^*} + C_2)}{(\mu_x^2 + \mu_{x^*}^2 + C_1)(\sigma_x^2 + \sigma_{x^*}^2 + C_2)}$$

261 where μ_x , μ_{x^*} and σ_x , σ_{x^*} , σ_{xx^*} are the mean and the standard deviation of x and x^* ,
 262 respectively. The positive constants C_1 and C_2 are used to avoid a null denominator, which
 263 are defaulted by the build-in ssim function.

264 **4.3. Results.** We make a detailed comparison of our method. More specifically, the meth-
265 ods with single net (S2HaarNet and DoubleS2haarNet) and the methods with plug-and-play
266 (S2HaarNetPnP and DoubleS2haarNetPnP) are compared. First of all, the three datasets
267 are tested. The results of datasets ‘F6’, ‘F7’, and ‘F8’ are listed in Table 2, from which we
268 know that the proposed methods are robust in different degradation. For example, when the
269 missing ratio is from 50% up to 95%, our methods always have competitive restoration results.
270 Besides, the results based on the plug-and-play approach are better than the one with only
271 CNN, which also illustrate the effectiveness of the proposed plug-and-play scheme. Moreover,
272 the testing of two different datasets and different combinations of the proposed model also
273 gives a strong validity to our scheme. On the other hand, five grey images are also tested
274 in this paper. We list the numerical results in Table 3, from which the plug-and-play-based
275 models also have better restoration results.

276 The visual results are present in Figures 5–?? with missing ratio 50%, 80%, 90%, 95%, respec-
277 tively. Figure 5 (a) is the observed image with a low missing ratio (50%). As we can see from
278 the results (b)–(e), most of the objects in the image are recovered. However, with detailed
279 observation, we know that the plug-and-play-based methods have more competitive perfor-
280 mance. With the missing ratio up to 80%, there are some outlines of the original image that

Figure 6. The inpainting results (PSNR (dB)/SSIM) with random missing ratio 80%. (a) the degraded image; the recovered results of (b) Haar network only; (c) plug and play with Haar network; (d) Double-S2Haar network only; (e) plug and play with Double-S2Haar network; (f) the original image.

281 can be seen in ?? (a). It turns out that the results of the S2HaarNet and Double-S2HaarNet
 282 have quite satisfactory results. As the plug-and-play is applied in (b) and (d) respectively,
 283 the results of inpainting are greatly improved. For the low sample ratio, from ?? (a) and ??
 284 (a), the details of the image are almost disappeared. With this low observation, our models
 285 also can recover the images with good quality. The above visual results demonstrate again
 286 the robustness and effectiveness of the proposed inpainting models.

287 The experiments on color images are also conducted in Figures ??–??. which illustrate the
 288 good generalization of our model to color images. Note that our results are slightly over-
 289 smoothed for lower sample rates, such as 95%. ?? shows that, in contrast to other results,
 290 our solutions can better restore the structures of images, which is consistent with the results
 291 of the majority of plug-and-play-based works.

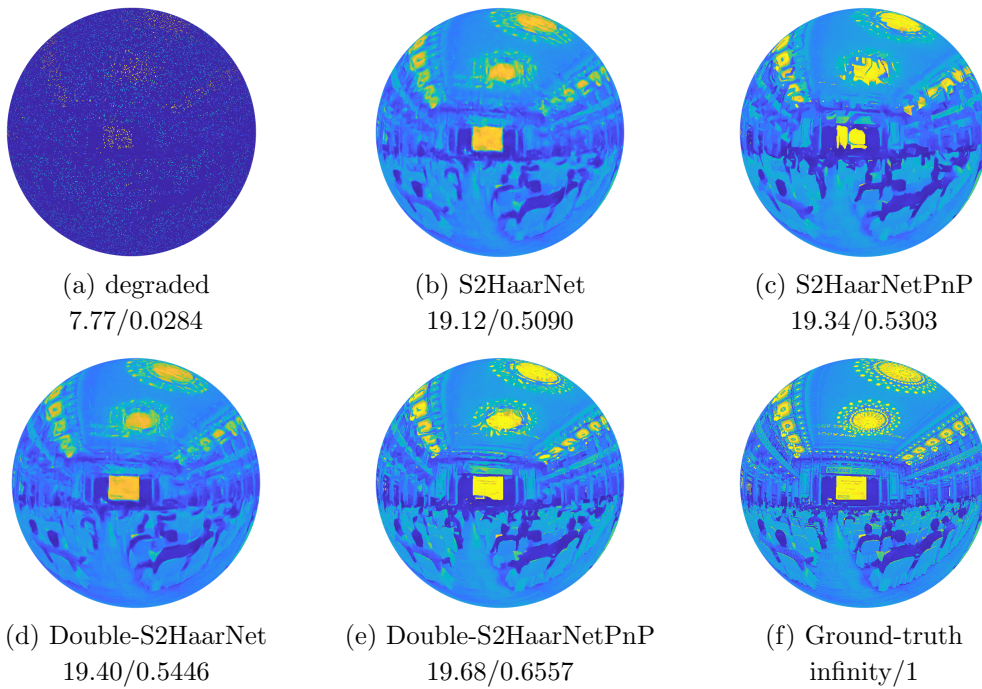

Figure 7. The inpainting results (PSNR (dB)/SSIM) with random missing ratio 90%. (a) the degraded image; the recovered results of (b) Haar network only; (c) plug and play with Haar network; (d) Double-S2Haar network only; (e) plug and play with Double-S2Haar network; (f) the original image.

292 **4.4. Ablation experiments.** In this section, to analyze the improvement effect of intro-
 293 ducing framelet transforms in image inpainting tasks, the following 3 variants of our model
 294 are designed for comparison: (a) random filters for constructing framelets, which is different
 295 from specifically designed directional framelets with respect to matrix (2.3); (b) max-pooling
 296 for downsampling and bilinear interpolation for upsampling; (c) average pooling for down-
 297 sampling and bilinear interpolation for upsampling. The comparison results are illustrated

Figure 12. The color image inpainting results (PSNR (dB)/SSIM) with random missing ratio 95%. Zoomed part of (a) the degraded image; the recovered results of (b) Haar network only; (c) plug and play with Haar network; (d) Double-S2Haar network only; (e) plug and play with Double-S2Haar network; (f) the original image.

298 in table 4, which shows the advantages by introducing framelet transforms, especially for the
 299 case of high inpainting rates.

300 **5. Conclusion and further remarks.** In this work, we presented a novel model, Double-
 301 S2HaarNetPnP model, for image inpainting. We remark that (a) low-rank framelet coefficient
 302 regularizer is introduced to learn, (b) a new denoiser Double-S2HaarNet for spherical image
 303 inpainting is proposed and in the experiments, it is powerful for inpainting task with the
 304 deep Plug-and-play framework, and (c) Directional spherical Haar framelet is employed to
 305 capture directional texture information to enhance the learning ability of the model and the
 306 neural network. Experiments evaluated on various images illustrate the performance of the
 307 proposed method for spherical image inpainting task. The main challenges of our work are to
 308 develop a proper hierarchical partition of a manifold and explore the corresponding convolution
 309 calculation. With them, the proposed model can be further generalized to other manifolds.
